About This Book .................................................................................................................................. xxxv

1. Related Information ............................................................................................................................ xxxv
2. How to Read the Syntax Diagrams ......................................................................................................... xxxv
3. Getting Help ........................................................................................................................................... xxxvi

3.1. The Rexx Language Association Mailing List ........................................................................... xxxvi
3.2. The Open Object Rexx SourceForge Site ................................................................................... xxxvii
3.3. comp.lang.rexx Newsgroup ....................................................................................................... xxxviii

1. Open Object Rexx General Concepts .................................................................................................. 1

1.1. What Is Object-Oriented Programming? ....................................................................................... 1
1.2. Modularizing Data ............................................................................................................................. 1
1.3. Modeling Objects ............................................................................................................................. 3
1.4. How Objects Interact ....................................................................................................................... 5
1.5. Methods ......................................................................................................................................... 5
1.6. Polymorphism ................................................................................................................................. 6
1.7. Classes and Instances ..................................................................................................................... 6
1.8. Data Abstraction .............................................................................................................................. 8
1.9. Subclasses, Superclasses, and Inheritance .................................................................................... 8

1.10. Structure and General Syntax ....................................................................................................... 9

1.10.1. Characters .................................................................................................................................... 9
1.10.2. Whitespace .................................................................................................................................. 10
1.10.3. Comments ................................................................................................................................... 10
1.10.4. Tokens ......................................................................................................................................... 12

1.10.4.1. Literal Strings ....................................................................................................................... 12
1.10.4.2. Hexadecimal Strings ........................................................................................................... 13
1.10.4.3. Binary Strings ..................................................................................................................... 13
1.10.4.4. Symbols .................................................................................................................................. 14
1.10.4.5. Numbers .................................................................................................................................. 14
1.10.4.6. Operator Characters ......................................................................................................... 15
1.10.4.7. Special Characters ............................................................................................................ 16
1.10.4.8. Example .................................................................................................................................. 16
1.10.5. Implied Semicolons ............................................................................................................... 16
1.10.6. Continuations ............................................................................................................................ 17

1.11. Terms, Expressions, and Operators ............................................................................................... 17

1.11.1. Terms and Expressions ............................................................................................................ 17
1.11.2. Operators .................................................................................................................................... 18

1.11.2.1. String Concatenation ........................................................................................................ 19
1.11.2.2. Arithmetic .......................................................................................................................... 19
1.11.2.3. Comparison ....................................................................................................................... 20
1.11.2.4. Logical (Boolean) ............................................................................................................ 21

1.11.3. Parentheses and Operator Precedence ..................................................................................... 21
1.11.4. Message Terms ....................................................................................................................... 23
1.11.5. Message Sequences ................................................................................................................. 25

1.12. Clauses and Instructions ................................................................................................................. 25

1.12.1. Null Clauses ............................................................................................................................... 26
1.12.2. Directives .................................................................................................................................. 26

About This Book

This book describes the Open Object Rexx Interpreter, called the interpreter or language processor in the following, and the object-oriented Rexx language.

This book is intended for people who plan to develop applications using Rexx. Its users range from the novice, who might have experience in some programming language but no Rexx experience, to the experienced application developer, who might have had some experience with Object Rexx.

This book is a reference rather than a tutorial. It assumes you are already familiar with object-oriented programming concepts.

Descriptions include the use and syntax of the language and explain how the language processor "interprets" the language as a program is running.

1. Related Information

See also: Open Object Rexx: Programming Guide

2. How to Read the Syntax Diagrams

Throughout this book, syntax is described using the structure defined below.

- Read the syntax diagrams from left to right, from top to bottom, following the path of the line.
  - The >>> symbol indicates the beginning of a statement.
  - The --- symbol indicates that the statement syntax is continued on the next line.
  - The >--- symbol indicates that a statement is continued from the previous line.
  - The ---< symbol indicates the end of a statement.
  - Diagrams of syntactical units other than complete statements start with the >--- symbol and end with the ---< symbol.
- Required items appear on the horizontal line (the main path).
  - >>>STATEMENT--required_item-------------------------------><
- Optional items appear below the main path.
  - >>>STATEMENT--+--------------------------><
    +optional_item+
- If you can choose from two or more items, they appear vertically, in a stack. If you must choose one of the items, one item of the stack appears on the main path.
  - >>>STATEMENT--+-required_choice1+-required_choice2--><
- If choosing one of the items is optional, the entire stack appears below the main path.
  - >>>STATEMENT--+-optional_choice1--><
3. Getting Help

The Open Object Rexx Project has a number of methods to obtain help for ooRexx. These methods, in no particular order of preference, are listed below.

3.1. The Rexx Language Association Mailing List

The Rexx Language Association (http://www.rexxla.org/) maintains a mailing list for its members. This mailing list is only available to RexxLA members thus you will need to join RexxLA in order to get on the list. The dues for RexxLA membership are small and are charged on a yearly basis. For details on joining RexxLA please refer to the RexxLA Home Page (http://rexxla.org/) or the RexxLA Membership Application (http://www.rexxla.org/rexxla/join.html) page.
3.2. The Open Object Rexx SourceForge Site

The Open Object Rexx Project (http://www.oorexx.org/) utilizes SourceForge (http://sourceforge.net/) to house the ooRexx Project (http://sourceforge.net/projects/oorexx) source repositories, mailing lists and other project features. Here is a list of some of the most useful facilities.

The ooRexx Forums

The ooRexx project maintains a set of forums that anyone may contribute to or monitor. They are located on the ooRexx Forums (http://sourceforge.net/forum/?group_id=119701) page. There are currently three forums available: Help, Developers and Open Discussion. In addition, you can monitor the forums via email.

The Developer Mailing List

You can subscribe to the oorexx-devel mailing list at ooRexx Mailing List Subscriptions (http://sourceforge.net/mail/?group_id=119701) page. This list is for discussing ooRexx project development activities and future interpreter enhancements. It also supports a historical archive of past messages.

The Users Mailing List

You can subscribe to the oorexx-users mailing list at ooRexx Mailing List Subscriptions (http://sourceforge.net/mail/?group_id=119701) page. This list is for discussing using ooRexx. It also supports a historical archive of past messages.

The Announcements Mailing List

You can subscribe to the oorexx-announce mailing list at ooRexx Mailing List Subscriptions (http://sourceforge.net/mail/?group_id=119701) page. This list is only used to announce significant ooRexx project events.

The Bug Mailing List

You can subscribe to the oorexx-bugs mailing list at ooRexx Mailing List Subscriptions (http://sourceforge.net/mail/?group_id=119701) page. This list is only used for monitoring changes to the ooRexx bug tracking system.

Bug Reports

You can create a bug report at ooRexx Bug Report (http://sourceforge.net/tracker/?group_id=119701&atid=684730) page. Please try to provide as much information in the bug report as possible so that the developers can determine the problem as quickly as possible. Sample programs that can reproduce your problem will make it easier to debug reported problems.

Request For Enhancement

You can suggest ooRexx features at the ooRexx Feature Requests (http://sourceforge.net/tracker/?group_id=119701&atid=684733) page.

Patch Reports

If you create an enhancement patch for ooRexx please post the patch using the ooRexx Patch Report (http://sourceforge.net/tracker/?group_id=119701&atid=684732) page. Please provide as much
information in the patch report as possible so that the developers can evaluate the enhancement as quickly as possible.

Please do not post bug patches here, instead you should open a bug report and attach the patch to it.

### 3.3. comp.lang.rexx Newsgroup

The comp.lang.rexx (news:comp.lang.rexx) newsgroup is a good place to obtain help from many individuals within the Rexx community. You can obtain help on Open Object Rexx or on any number of other Rexx interpreters and tools.
Chapter 1. Open Object Rexx General Concepts

The Rexx language is particularly suitable for:

- Application scripting
- Command procedures
- Application front ends
- User-defined macros (such as editor subcommands)
- Prototyping
- Personal computing

As an object-oriented language, Rexx provides data encapsulation, polymorphism, an object class hierarchy, class-based inheritance of methods, and concurrency. It includes a number of useful base classes and allows you create new object classes of your own.

Open Object Rexx is compatible with earlier Rexx versions, both non-object based Rexx and IBM’s Object Rexx. It has the usual structured-programming instructions, for example IF, SELECT, DO WHILE, and LEAVE, and a number of useful built-in functions.

The language imposes few restrictions on the program format. There can be more than one clause on a line, or a single clause can occupy more than one line. Any indentation scheme is allowed. You can, therefore, code programs in a format that emphasizes their structure, making them easier to read.

There is no limit to the size of variable values, as long as all values fit into the storage available. There are no restrictions on the types of data that variables can contain.

A language processor (interpreter) runs Rexx programs. That is, the program runs line by line and word by word, without first being translated to machine language (compiled.) One of the advantages of this is that you can fix the error and rerun the program faster than when using a compiler.

Note: Open Object Rexx also supplies the rexxc program that can be used to tokenize Rexx programs. Tokenizing a program is not the same as compiling a program to machine language. See Appendix A. Distributing Programs without Source of the Open Object Rexx Programming Guide for details on rexxc and tokenizing.

1.1. What Is Object-Oriented Programming?

Object-oriented programming is a way to write computer programs by focusing not on the instructions and operations a program uses to manipulate data, but on the data itself. First, the program simulates, or models, objects in the physical world as closely as possible. Then the objects interact with each other to produce the desired result.

Real-world objects, such as a company’s employees, money in a bank account, or a report, are stored as data so the computer can act upon it. For example, when you print a report, print is the action and report is the object acted upon. Essentially, the objects are the "nouns", while the actions are the "verbs".
1.2. Modularizing Data

In conventional, structured programming, actions like print are often isolated from the data by placing them in subroutines or modules. A module typically contains an operation for implementing one simple action. You might have a PRINT module, a SEND module, an ERASE module. The data these modules operate on must be constructed by the programmer and passed to the modules to perform an action.

PROGRAM ...
---------------------------------------------
---------------------------------------------
   PRINT -----------------
---------------------------------------------
---------------------------------------------
---------------------------------------------
---------------------------------------------
---------------------------------------------
---------------------------------------------
   SEND -----------------
---------------------------------------------
---------------------------------------------
---------------------------------------------
---------------------------------------------
---------------------------------------------
---------------------------------------------
   ERASE -----------------
---------------------------------------------
---------------------------------------------
---------------------------------------------

But with object-oriented programming, it is the data that is modularized. And each data module includes its own operations for performing actions directly related to its data. The programmer that uses the objects need only be aware of the operations an object performs and not how the data is organized internally.
In the case of report, the report object would contain its own built-in PRINT, SEND, ERASE, and FILE operations.

Object-oriented programming lets you model real-world objects—even very complex ones—precisely and elegantly. As a result, object manipulation becomes easier and computer instructions become simpler and can be modified later with minimal effort.

Object-oriented programming hides any information that is not important for acting on an object, thereby concealing the object’s complexities. Complex tasks can then be initiated simply, at a very high level.

1.3. Modeling Objects

In object-oriented programming, objects are modeled to real-world objects. A real-world object has actions related to it and characteristics of its own.

Take a ball, for example. A ball can be acted on—rolled, tossed, thrown, bounced, caught. But it also has its own physical characteristics—size, shape, composition, weight, color, speed, position. An accurate data model of a real ball would define not only the physical characteristics but all related actions and characteristics in one package:
In object-oriented programming, objects are the basic building blocks—the fundamental units of data. There are many kinds of objects; for example, character strings, collections, and input and output streams. An object—such as a character string—always consists of two parts: the possible actions or operations related to it, and its characteristics or variables. A variable has a name, and an associated data value that can change over time. The variables represent the internal state of the object, and can be directly accessed only by the code that implements the object’s actions.

Figure 1-3. Ball Object with Variable Names and Values

To access an object’s data, you must always specify an action. For example, suppose the object is the number 5. Its actions might include addition, subtraction, multiplication, and division. Each of these actions is an interface to the object’s data. The data is said to be encapsulated because the only way to access it is through one of these surrounding actions. The encapsulated internal characteristics of an object are its variables. The variables are associated with an object and exist for the lifetime of that object:
1.4. How Objects Interact

The actions defined by an object are its only interface to other objects. Actions form a kind of "wall" that encapsulates the object, and shields its internal information from outside objects. This shielding is called information hiding. Information hiding protects an object’s data from corruption by outside objects, and also protects outside objects from relying on another object’s private data, which can change without warning.

One object can act upon another (or cause it to act) only by calling that object’s actions, namely by sending messages. Objects respond to these messages by performing an action, returning data, or both. A message to an object must specify:

- A receiving object
- The "message send" symbol, ~, which is called the twiddle
- The action and, optionally in parentheses, any parameters required by the action

So the message format looks like this:

object~action(parameters)

Assume that the object is the string !iH. Sending it a message to use its REVERSE action:

"!iH"~reverse

returns the string object Hi!.
Chapter 1. Open Object Rexx General Concepts

1.5. Methods

Sending a message to an object results in performing some action; that is, it executes some underlying code. The action-generating code is called a method. When you send a message to an object, the message is the name of the target method. Method names are character strings like REVERSE. In the preceding example, sending the reverse message to the \(^i\text{Hi}\) object causes it to run the REVERSE method. Most objects are capable of more than one action, and so have a number of available methods.

The classes Rexx provides include their own predefined methods. The Message class, for example, has the COMPLETED, INIT, NOTIFY, RESULT, SEND, and START methods. When you create your own classes, you can write new methods for them in Rexx code. Much of the object programming in Rexx is writing the code for the methods you create.

1.6. Polymorphism

Rexx lets you send the same message to objects that are different:

```
"!iH"~reverse /* Reverses the characters \"!iH\" to form \"Hi!\" */
pen~reverse /* Reverses the direction of a plotter pen */
ball~reverse /* Reverses the direction of a moving ball */
```

As long as each object has its own REVERSE method, REVERSE runs even if the programming implementation is different for each object. This ability to hide different functions behind a common interface is called polymorphism. As a result of information hiding, each object in the previous example knows only its own version of REVERSE. And even though the objects are different, each reverses itself as dictated by its own code.

Although the \(^i\text{Hi}\) object’s REVERSE code is different from the plotter pen’s, the method name can be the same because Rexx keeps track of the methods each object owns. The ability to reuse the same method name so that one message can initiate more than one function is another feature of polymorphism. You do not need to have several message names like REVERSE_STRING, REVERSE_PEN, REVERSE_BALL. This keeps method-naming schemes simple and makes complex programs easy to follow and modify.

The ability to hide the various implementations of a method while leaving the interface the same illustrates polymorphism at its lowest level. On a higher level, polymorphism permits extensive code reuse.

1.7. Classes and Instances

In Rexx, objects are organized into classes. Classes are like templates; they define the methods and variables that a group of similar objects have in common and store them in one place.

If you write a program to manipulate some screen icons, for example, you might create an Icon class. In that Icon class you can include all the icon objects with similar actions and characteristics:
All the icon objects might use common methods like DRAW or ERASE. They might contain common variables like position, color, or size. What makes each icon object different from one another is the data assigned to its variables. For the Windows system icon, it might be position="20,20", while for the shredder it is "20,30" and for information it is "20,40":

Objects that belong to a class are called *instances* of that class. As instances of the Icon class, the Windows system icon, shredder icon, and information icon *acquire* the methods and variables of that class. Instances behave as if they each had their own methods and variables of the same name. All instances, however, have their own unique properties—the *data* associated with the variables. Everything else can be stored at the class level.
If you must update or change a particular method, you only have to change it at one place, at the class level. This single update is then acquired by every new instance that uses the method.

A class that can create instances of an object is called an object class. The Icon class is an object class you can use to create other objects with similar properties, such as an application icon or a drives icon. An object class is like a factory for producing instances of the objects.

1.8. Data Abstraction

The ability to create new, high-level data types and organize them into a meaningful class structure is called data abstraction. Data abstraction is at the core of object-oriented programming. Once you model objects with real-world properties from the basic data types, you can continue creating, assembling, and combining them into increasingly complex objects. Then you can use these objects as if they were part of the original programming language.

1.9. Subclasses, Superclasses, and Inheritance

When you write your first object-oriented program, you do not have to begin your real-world modeling from scratch. Rexx provides predefined classes and methods. From there you can create additional classes and methods of your own, according to your needs.

Rexx classes are hierarchical. Any subclass (a class below another class in the hierarchy) inherits the methods and variables of one or more superclasses (classes above a class in the hierarchy):
You can add a class to an existing superclass. For example, you might add the Icon class to the Screen-Object superclass:

In this way, the subclass inherits additional methods from the superclass. A class can have more than one superclass, for example, subclass Bitmap might have the superclasses Screen-Object and Art-Object. Acquiring methods and variables from more than one superclass is known as multiple inheritance:

1.10. Structure and General Syntax

A Rexx program is built from a series of clauses that are composed of:

- Zero or more whitespace characters (blank or horizontal tabs) (which are ignored)
- A sequence of tokens (see Tokens)
- Zero or more whitespace characters (again ignored)
- A semicolon (;) delimiter that the line end, certain keywords, or the colon (:) implies.

Conceptually, each clause is scanned from left to right before processing, and the tokens composing it are identified. Instruction keywords are recognized at this stage, comments are removed, and sequences of whitespace characters (except within literal strings) are converted to single blanks. Whitespace characters adjacent to operator characters and special characters are also removed.
1.10.1. Characters

A character is a member of a defined set of elements that is used for the control or representation of data. You can usually enter a character with a single keystroke. The coded representation of a character is its representation in digital form. A character, the letter A, for example, differs from its coded representation or encoding. Various coded character sets (such as ASCII and EBCDIC) use different encodings for the letter A (decimal values 65 and 193, respectively). This book uses characters to convey meanings and not to imply a specific character code, except where otherwise stated. The exceptions are certain built-in functions that convert between characters and their representations. The functions C2D, C2X, D2C, X2C, and XRANGE depend on the character set used.

A code page specifies the encodings for each character in a set. Be aware that:

- Some code pages do not contain all characters that Rexx defines as valid (for example, the logical NOT character).
- Some characters that Rexx defines as valid have different encodings in different code pages, for example the exclamation mark (!).

1.10.2. Whitespace

A whitespace character is one that the interpreter recognizes as a "blank" or "space" character. There are two characters used by Rexx as whitespace that can be used interchangeably:

(blank)
A "blank" or "space" character. This is represented by '20'X in ASCII implementations.

(horizontal tab)
A "tab". This is represented by '09'X in ASCII implementations.

Horizontal tabs encountered in Rexx program source are converted into blanks, allowing tab characters and blanks to be use interchangeably in source. Additionally, Rexx operations such as the PARSE instruction or the SUBWORD() built-in function will also accept either blank or tab characters as word delimiters.

1.10.3. Comments

A comment is a sequence of characters delimited by specific characters. It is ignored by the program but acts as a separator. For example, a token containing one comment is treated as two tokens.

The interpreter recognizes the following types of comments:

- A line comment, where the comment is limited to one line
- The standard Rexx comment, where the comment can cover several lines

A line comment is started by two subsequent minus signs (--) and ends at the end of a line. Example:
Chapter 1. Open Object Rexx General Concepts

"Fred"
"Don't Panic!"
'You shouldn't' -- Same as "You shouldn't"
"
In this example, the language processor processes the statements from 'Fred' to 'You shouldn\'t', ignores the words following the line comment, and continues to process the statement "".

A standard comment is a sequence of characters (on one or more lines) delimited by /* and */. Within these delimiters any characters are allowed. Standard comments can contain other standard comments, as long as each begins and ends with the necessary delimiters. They are called nested comments. Standard comments can be anywhere and of any length.

/* This is an example of a valid Rexx comment */

Take special care when commenting out lines of code containing /* or */ as part of a literal string. Consider the following program segment:

```rexx
01 parse pull input
02 if substr(input,1,5) = "/*123"
03 then call process
04 dept = substr(input,32,5)
```

To comment out lines 2 and 3, the following change would be incorrect:

```rexx
01 parse pull input
02 /* if substr(input,1,5) = "/*123"
03 then call process
04 */ dept = substr(input,32,5)
```

This is incorrect because the language processor would interpret the /* that is part of the literal string /*123 as the start of a nested standard comment. It would not process the rest of the program because it would be looking for a matching standard comment end (*/).

You can avoid this type of problem by using concatenation for literal strings containing /* or */; line 2 would be:

```rexx
if substr(input,1,5) = "/|| "*123"
```

You could comment out lines 2 and 3 correctly as follows:

```rexx
01 parse pull input
02 /* if substr(input,1,5) = "/|| "*123"
03 then call process
04 */ dept = substr(input,32,5)
```

Both types of comments can be mixed and nested. However, when you nest the two types, the type of comment that comes first takes precedence over the one nested. Here is an example:

"Fred"
"Don't Panic!"
'You shouldn\'t' /* Same as "You shouldn\'t"
"" -- The null string */
Chapter 1. Open Object Rexx General Concepts

In this example, the language processor ignores everything after ‘You shouldn’t’ up to the end of the last line. In this case, the standard comment has precedence over the line comment.

When nesting the two comment types, make sure that the start delimiter of the standard comment /* is not in the line commented out with the line comment signs.

Example:

"Fred"
"Don't Panic!"
'You shouldn't'
 /* Same as /* "You shouldn't"
"" The null string */

This example produces an error because the language processor ignores the start delimiter of the standard comment, which is commented out using the line comment.

1.10.4. Tokens

A token is the unit of low-level syntax from which clauses are built. Programs written in Rexx are composed of tokens. Tokens can be of any length, up to an implementation-restricted maximum. They are separated by whitespace or comments, or by the nature of the tokens themselves. The classes of tokens are:

- Literal strings
- Hexadecimal strings
- Binary strings
- Symbols
- Numbers
- Operator characters
- Special characters

1.10.4.1. Literal Strings

A literal string is a sequence including any characters except line feed (X"10") and delimited by a single quotation mark (') or a double quotation mark ("). You use two consecutive double quotation marks (""") to represent one double quotation mark (") within a string delimited by double quotation marks. Similarly, you use two consecutive single quotation marks ("') to represent one single quotation mark (') within a string delimited by single quotation marks. A literal string is a constant and its contents are never modified when it is processed. Literal strings must be complete on a single line. This means that unmatched quotation marks can be detected on the line where they occur.

A literal string with no characters (that is, a string of length 0) is called a null string.

These are valid strings:

"Fred"
"Don't Panic!"
'You shouldn't'
 /* Same as "You shouldn't" */
Chapter 1. Open Object Rexx General Concepts

Implementation maximum: A literal string has no upper bound on the number of characters, limited on by available memory.

Note that a string immediately followed by a left parenthesis is considered to be the name of a function. If immediately followed by the symbol X or x, it is considered to be a hexadecimal string. If followed immediately by the symbol B or b, it is considered to be a binary string.

1.10.4.2. Hexadecimal Strings

A hexadecimal string is a literal string, expressed using a hexadecimal notation of its encoding. It is any sequence of zero or more hexadecimal digits (0-9, a-f, A-F), grouped in pairs. A single leading 0 is assumed, if necessary, at the beginning of the string to make an even number of hexadecimal digits. The groups of digits are optionally separated by one or more whitespace characters, and the whole sequence is delimited by single or double quotation marks and immediately followed by the symbol X or x. Neither x nor X can be part of a longer symbol. The whitespace characters, which can only be byte boundaries (and not at the beginning or end of the string), are to improve readability. The language processor ignores them.

A hexadecimal string is a literal string formed by packing the hexadecimal digits given. Packing the hexadecimal digits removes whitespace and converts each pair of hexadecimal digits into its equivalent character, for example, "41"X to A.

Hexadecimal strings let you include characters in a program even if you cannot directly enter the characters themselves. These are valid hexadecimal strings:

"ABCD"x
"1d ec f8"X
"1 d8"x

Note: A hexadecimal string is not a representation of a number. It is an escape mechanism that lets a user describe a character in terms of its encoding (and, therefore, is machine-dependent). In ASCII, "20"X is the encoding for a blank. In every case, a string of the form "....."x is an alternative to a straightforward string. In ASCII "41"x and "A" are identical, as are "20"x and a blank, and must be treated identically.

Implementation maximum: The packed length of a hexadecimal string (the string with whitespace removed) is unlimited.

1.10.4.3. Binary Strings

A binary string is a literal string, expressed using a binary representation of its encoding. It is any sequence of zero or more binary digits (0 or 1) in groups of 8 (bytes) or 4 (nibbles). The first group can have less than four digits; in this case, up to three 0 digits are assumed to the left of the first digit, making a total of four digits. The groups of digits are optionally separated by one or more whitespace characters, and the whole sequence is delimited by matching single or double quotation marks and immediately followed by the symbol b or B. Neither b nor B can be part of a longer symbol. The whitespace
Chapter 1. Open Object Rexx General Concepts

characters, which can only be byte or nibble boundaries (and not at the beginning or end of the string), are to improve readability. The language processor ignores them.

A binary string is a literal string formed by packing the binary digits given. If the number of binary digits is not a multiple of 8, leading zeros are added on the left to make a multiple of 8 before packing. Binary strings allow you to specify characters explicitly, bit by bit. These are valid binary strings:

```
"11110000"b /* == "f0"x */
"101 1101"b  /* == "5d"x */
"1"b     /* == "00000001"b and "01"x */
"10000 10101010"b  /* == "0001 0000 1010 1010"b */
""b  /* == "" */
```

**Implementation maximum:** The packed length of a binary-literal string is unlimited.

1.10.4.4. Symbols

Symbols are groups of characters, selected from the:

- English alphabetic characters (A-Z and a-z).
- Numeric characters (0-9)
- Characters . ! ? and underscore (_).

Any lowercase alphabetic character in a symbol is translated to uppercase (that is, lowercase a-z to uppercase A-Z) before use.

These are valid symbols:

Fred
Albert.Hall
WHERE?

If a symbol does not begin with a digit or a period, you can use it as a variable and can assign it a value. If you have not assigned a value to it, its value is the characters of the symbol itself, translated to uppercase (that is, lowercase a-z to uppercase A-Z). Symbols that begin with a number or a period are constant symbols and cannot directly be assigned a value. (See Environment Symbols.)

One other form of symbol is allowed to support the representation of numbers in exponential format. The symbol starts with a digit (0-9) or a period, and it can end with the sequence E or e, followed immediately by an optional sign (- or +), followed immediately by one or more digits (which cannot be followed by any other symbol characters). The sign in this context is part of the symbol and is not an operator.

These are valid numbers in exponential notation:

```
17.3E-12
.03e+9
```
1.10.4.5. Numbers

Numbers are character strings consisting of one or more decimal digits, with an optional prefix of a plus (+) or minus (-) sign, and optionally including a single period (.) that represents a decimal point. A number can also have a power of 10 suffixed in conventional exponential notation: an E (uppercase or lowercase), followed optionally by a plus or minus sign, then followed by one or more decimal digits defining the power of 10. Whenever a character string is used as a number, rounding can occur to a precision specified by the NUMERIC DIGITS instruction (the default is nine digits). See Numbers and Arithmetic for a full definition of numbers.

Numbers can have leading whitespace (before and after the sign) and trailing whitespace. Whitespace characters cannot be embedded among the digits of a number or in the exponential part. Note that a symbol or a literal string can be a number. A number cannot be the name of a variable.

These are valid numbers:

12
"-17.9"
127.0650
73e+128
" + 7.9E5 "

You can specify numbers with or without quotation marks around them. Note that the sequence -17.9 (without quotation marks) in an expression is not simply a number. It is a minus operator (which can be prefix minus if no term is to the left of it) followed by a positive number. The result of the operation is a number, which might be rounded or reformatted into exponential form depending on the size of the number and the current NUMERIC DIGITS setting.

A whole number is a number that has no decimal part and that the language processor would not usually express in exponential notation. That is, it has no more digits before the decimal point than the current setting of NUMERIC DIGITS.

Implementation maximum: The exponent of a number expressed in exponential notation can have up to nine digits.

1.10.4.6. Operator Characters

The characters + - / % * & = < > <= >= == /= //= && || ** ¬ > < and the sequences += -= *= /= %= //= ||= &= |= |&&== > >> = are also used in parsing templates, and the equal sign and the sequences +=, -=, *= /=, %=, /=, ||=, &=. k=. |=, and && are also used to indicate assignment. Whitespace characters adjacent to operator characters are removed. Therefore, the following are identical in meaning:

345>=123
345 >=123
345 >= 123
345 > = 123

Some of these characters (and some special characters—see the next section) might not be available in all character sets. In this case, appropriate translations can be used. In particular, the vertical bar (|) is often shown as a split vertical bar (¦).
Chapter 1. Open Object Rexx General Concepts

**Note:** The Rexx interpreter uses ASCII character 124 in the concatenation operator and as the logical OR operator. Depending on the code page or keyboard for your particular country, ASCII 124 can be shown as a solid vertical bar (|) or a split vertical bar (¦). The character on the screen might not match the character engraved on the key. If you receive error 13, *Invalid character in program*, on an instruction including a vertical bar character, make sure this character is ASCII 124.

Throughout the language, the NOT (¬) character is synonymous with the backslash (\). You can use the two characters interchangeably according to availability and personal preference.

The Rexx interpreter recognizes both ASCII character 170 (‘AA’X) and ASCII character 172 (‘AC’X) for the logical NOT operator. Depending on your country, the ¬ might not appear on your keyboard. If the character is not available, you can use the backslash (\) in place of ¬.

### 1.10.4.7. Special Characters

The following characters, together with the operator characters, have special significance when found outside of literal strings:

```
, ; : ( ) [ ] ~
```

These characters constitute the set of special characters. They all act as token delimiters, and whitespace characters (blank or horizontal tab) adjacent to any of these are removed. There is an exception: a whitespace character adjacent to the outside of a parenthesis or bracket is deleted only if it is also adjacent to another special character (unless the character is a parenthesis or bracket and the whitespace character is outside it, too). For example, the language processor does not remove the blank in `A(Z)`. This is a concatenation that is not equivalent to `A(Z)`, a function call. The language processor removes the blanks in `(A) + (Z)` because this is equivalent to `(A)+(Z)`.

### 1.10.4.8. Example

The following example shows how a clause is composed of tokens:

```
"REPEAT" A + 3;
```

This example is composed of six tokens—a literal string ("REPEAT"), a blank operator, a symbol (A, which can have an assigned value), an operator (+), a second symbol (3, which is a number and a symbol), and the clause delimiter (;). The blanks between the A and the + and between the + and the 3 are removed. However, one of the blanks between the "REPEAT" and the A remains as an operator. Thus, this clause is treated as though written:

```
"REPEAT" A+3;
```

### 1.10.5. Implied Semicolons

The last element in a clause is the semicolon (;) delimiter. The language processor implies the semicolon at a line end, after certain keywords, and after a colon if it follows a single symbol. This means that you
need to include semicolons only when there is more than one clause on a line or to end an instruction whose last character is a comma.

A line end usually marks the end of a clause and, thus, Rexx implies a semicolon at most end of lines. However, there are the following exceptions:

- The line ends in the middle of a comment. The clause continues on to the next line.
- The last token was the continuation character (a comma or a minus sign) and the line does not end in the middle of a comment. (Note that a comment is not a token.)

Rexx automatically implies semicolons after colons (when following a single symbol or literal string, a label) and after certain keywords when they are in the correct context. The keywords that have this effect are ELSE, OTHERWISE, and THEN. These special cases reduce typographical errors significantly.

Note: The two characters forming the comment delimiters, /* and */, must not be split by a line end (that is, / and * should not appear on different lines) because they could not then be recognized correctly; an implied semicolon would be added.

1.10.6. Continuations

One way to continue a clause on the next line is to use the comma or the minus sign (-), which is referred to as the continuation character. The continuation character is functionally replaced by a blank, and, thus, no semicolon is implied. One or more comments can follow the continuation character before the end of the line.

The following example shows how to use the continuation character to continue a clause:

```rexx
say "You can use a comma", -- this line is continued "to continue this clause."
```
or

```rexx
say "You can use a minus"--, -- this line is continued "to continue this clause."
```

1.11. Terms, Expressions, and Operators

Expressions in Rexx are a general mechanism for combining one or more pieces of data in various ways to produce a result, usually different from the original data. All expressions evaluate to objects.

Everything in Rexx is an object. Rexx provides some objects, which are described in later sections. You can also define and create objects that are useful in particular applications—for example, a menu object for user interaction. See Modeling Objects for more information.
1.11.1. Terms and Expressions

Terms are literal strings, symbols, message terms, function calls, or subexpressions interspersed with zero or more operators that denote operations to be carried out on terms.

Literal strings, which are delimited by quotation marks, are constants.

Symbols (no quotation marks) are translated to uppercase. A symbol that does not begin with a digit or a period can be the name of a variable; in this case the value of that variable is used. A symbol that begins with a period can identify an object that the current environment provides; in this case, that object is used. Otherwise a symbol is treated as a constant string. A symbol can also be compound.

Message terms are described in Message Terms.

Function calls (see Functions), which are of the following form:

```
+-,------------------+
 |   V |                |
 >>-symbolorstring(--+-+----<)-----------------------><
       +-expression-+
```

The symbolorstring is a symbol or literal string.

An expression consists of one or more terms. A subexpression is a term in an expression surrounded with a left and a right parenthesis.

Evaluation of an expression is left to right, modified by parentheses and operator precedence in the usual algebraic manner (see Parentheses and Operator Precedence). Expressions are wholly evaluated, unless an error occurs during evaluation.

As each term is used in an expression, it is evaluated as appropriate. The result is an object. Consequently, the result of evaluating any expression is itself an object (such as a character string).

1.11.2. Operators

An operator is a representation of an operation, such as an addition, to be carried out on one or two terms. Each operator, except for the prefix operators, acts on two terms, which can be symbols, strings, function calls, message terms, intermediate results, or subexpressions. Each prefix operator acts on the term or subexpression that follows it. Whitespace characters (and comments) adjacent to operator characters have no effect on the operator; thus, operators constructed from more than one character can have embedded whitespace and comments. In addition, one or more whitespace characters, if they occur in expressions but are not adjacent to another operator, also act as an operator. The language processor functionally translates operators into message terms. For dyadic operators, which operate on two terms, the language processor sends the operator as a message to the term on the left, passing the term on the right as an argument. For example, the sequence

```
>say 1+2
```

is functionally equivalent to:

```
>say 1""+("2")
```
Chapter 1. Open Object Rexx General Concepts

The blank concatenation operator sends the message " " (a single blank), and the abuttal concatenation operator sends the "" message (a null string). When the ¬ character is used in an operator, it is changed to a \. That is, the operators ¬= and \= both send the message \= to the target object.

For an operator that works on a single term (for example, the prefix - and prefix + operators), Rexx sends a message to the term, with no arguments. This means ¬z has the same effect as z""-"".

See Operator Methods for operator methods of the Object class and Arithmetic Methods for operator methods of the String class.

There are four types of operators:

- Concatenation
- Arithmetic
- Comparison
- Logical

1.11.2.1. String Concatenation

The concatenation operators combine two strings to form one string by appending the second string to the right-hand end of the first string. The concatenation may occur with or without an intervening blank. The concatenation operators are:

(b) Concatenate terms with one blank in between
|| Concatenate without an intervening blank
(ab) Concatenate without an intervening blank

You can force concatenation without a blank by using the || operator.

The abuttal operator is assumed between two terms that are not separated by another operator. This can occur when two terms are syntactically distinct, such as a literal string and a symbol, or when they are only separated by a comment.

Examples:

An example of syntactically distinct terms is: if Fred has the value 37.4, then Fred"%" evaluates to 37.4%.

If the variable PETER has the value 1, then (Fred) (Peter) evaluates to 37.41.

The two adjoining strings, one hexadecimal and one literal, "4a 4b"x"LMN" evaluate to JKLNM.

In the case of

Fred/* The NOT operator precedes Peter. */¬Peter

there is no abuttal operator implied, and the expression is not valid. However,

(Fred)/* The NOT operator precedes Peter. */(¬Peter)

results in an abuttal, and evaluates to 37.40.
1.11.2.2. Arithmetic

You can combine character strings that are valid numbers (see Numbers) using the following arithmetic operators:

- **Add**
- **Subtract**
- **Multiply**
- **Divide**
- **Integer divide** (divide and return the integer part of the result)
- **Remainder** (divide and return the remainder—not modulo, because the result can be negative)
- **Power** (raise a number to a whole-number power)

Prefix -  Same as the subtraction: 0 - number
Prefix +  Same as the addition: 0 + number

See Numbers and Arithmetic for details about precision, the format of valid numbers, and the operation rules for arithmetic. Note that if an arithmetic result is shown in exponential notation, it is likely that rounding has occurred.

1.11.2.3. Comparison

The comparison operators compare two terms and return the value 1 if the result of the comparison is true, or 0 otherwise.

The strict comparison operators all have one of the characters defining the operator doubled. The **==**, **\==**, and **\==** operators test for an exact match between two strings. The two strings must be identical (character by character) and of the same length to be considered strictly equal. Similarly, the strict comparison operators such as **>>** or **<<** carry out a simple character-by-character comparison, with no padding of either of the strings being compared. The comparison of the two strings is from left to right. If one string is shorter than the other and is a leading substring of another, then it is smaller than (less than) the other. The strict comparison operators also do not attempt to perform a numeric comparison on the two operands.

For all other comparison operators, if both terms involved are numeric, a numeric comparison (see Numeric Comparisons) is effected. Otherwise, both terms are treated as character strings, leading and trailing whitespace characters are ignored, and the shorter string is padded with blanks on the right.

Character comparison and strict comparison operations are both case-sensitive, and the exact collating order might depend on the character set used for the implementation. In an ASCII environment, such as Windows and *nix, the ASCII character value of digits is lower than that of the alphabetic characters, and that of lowercase alphabetic characters is higher than that of uppercase alphabetic characters.

The comparison operators and operations are:

- **=**  True if the terms are equal (numerically or when padded)
- **\=, \==** True if the terms are not equal (inverse of =)
- **>**  Greater than
Chapter 1. Open Object Rexx General Concepts

< Less than

>= Greater than or equal to

\<, \< Not less than

<= Less than or equal to

\>, \> Not greater than

== True if terms are strictly equal (identical)

\==, \== True if the terms are not strictly equal (inverse of ==)

>> Strictly greater than

<< Strictly less than

\<>, \<< Strictly not less than

\<=, \<= Strictly less than or equal to

\>>, \>> Strictly not greater than

Note: Throughout the language, the NOT (¬) character is synonymous with the backslash(\). You can use the two characters interchangeably, according to availability and personal preference. The backslash can appear in the following operators: \ (prefix not), \=, \==, \<=, \>, \><, \, and \>>.

1.11.2.4. Logical (Boolean)

A character string has the value false if it is 0, and true if it is 1. The logical operators take one or two such values and return 0 or 1 as appropriate. Values other than 0 or 1 are not permitted.

& AND — returns 1 if both terms are true.

| Inclusive OR — returns 1 if either term or both terms are true.

&& Exclusive OR — returns 1 if either term, but not both terms, is true.

Prefix \, ¬ Logical NOT — negates; 1 becomes 0, and 0 becomes 1.

1.11.3. Parentheses and Operator Precedence

Expression evaluation is from left to right; parentheses and operator precedence modify this:

- When parentheses are encountered—other than those that identify the arguments on messages (see Message Terms) and function calls—the entire subexpression between the parentheses is evaluated immediately when the term is required.

- When the sequence
term1 operator1 term2 operator2 term3

is encountered, and operator2 has precedence over operator1, the subexpression (term2 operator2
term3) is evaluated first.

Note, however, that individual terms are evaluated from left to right in the expression (that is, as soon
as they are encountered). The precedence rules affect only the order of operations.

For example, \* (multiply) has a higher priority than + (add), so 3+2*5 evaluates to 13 (rather than the 25
that would result if a strict left-to-right evaluation occurred). To force the addition to occur before the
multiplication, you could rewrite the expression as (3+2)*5. Adding the parentheses makes the first three
tokens a subexpression. Similarly, the expression -3**2 evaluates to 9 (instead of -9) because the prefix
minus operator has a higher priority than the power operator.

The order of precedence of the operators is (highest at the top):

```
~ ~--\  (message send)
+ - ~ \  (prefix operators)
**  (power)
* / % // (multiply and divide)
+ - (add and subtract)
(blank) || (abuttal) (concatenation with or without blank)
== >> << (comparison operators)

\= =~
>< <>
|> ->
|< ~<
|\>= ===
|\>> ~>>
|>< ~<<
>= >>==
<= <<==
&  (and)
l | && (or, exclusive or)
```

Examples:

Suppose the symbol A is a variable whose value is 3, DAY is a variable whose value is Monday, and other
variables are uninitialized. Then:

```
A+5 -> "8"
A-4+2 -> "-5"
A/2 -> "1.5"
0.5**2 -> "0.25"
(A+1)>7 -> "0" /* that is, False */
" ==" -> "1" /* that is, True */
```
Chapter 1. Open Object Rexx General Concepts

"==" -> "0" /* that is, False */
"\nn=" -> "1"
/* that is, True */
(A+1)*3=12 -> "1" /* that is, True */
"077">"11" -> "1" /* that is, True */
"077" >> "11" -> "0" /* that is, False */
"abc" >> "ab" -> "1" /* that is, True */
"abc" << "abd" -> "1" /* that is, True */
"ab" << "abd" -> "1" /* that is, True */

Today is Day -> "TODAY IS Monday"
"If it is" day -> "If it is Monday"
Substr(Day,2,3) -> "ond" /* Substr is a function */
"!"xxx"!" -> "!XXX!"

Note: The Rexx order of precedence usually causes no difficulty because it is the same as in conventional algebra and other computer languages. There are two differences from common notations:

- The prefix minus operator always has a higher priority than the power operator.
- Power operators (like other operators) are evaluated from left to right.

For example:

-3**2 == 9 /* not -9 */
-(2+1)**2 == 9 /* not -9 */
2**2**3 == 64 /* not 256 */

1.11.4. Message Terms

You can include messages to objects in an expression wherever a term, such as a literal string, is valid. A message can be sent to an object to perform an action, obtain a result, or both.

A message term can have one of the following forms:

```
>>>-receiver-+- messagename-+-expression->
```

For example:

```
>>>-receiver-[+-expression->]
```

ooRexx Reference Version 4.0.0
The receiver is a term (see Terms and Expressions for a definition of term). It receives the message. The ~ or ~~ indicates sending a message. The messagename is a literal string or a symbol that is taken as a constant. The expressions (separated by commas) between the parentheses or brackets are the arguments for the message. The receiver and the argument expressions can themselves include message terms. If the message has no arguments, you can omit the parentheses.

The left parenthesis, if present, must immediately follow a token (messagename or symbol) with no blank in between them. Otherwise, only the first part of the construct is recognized as a message term. (A blank operator would be assumed at that point.) Only a comment (which has no effect) can appear between a token and the left parenthesis.

You can use any number of expressions, separated by commas. The expressions are evaluated from left to right and form the arguments during the execution of the called method. Any ARG, PARSE ARG, or USE ARG instruction or ARG() built-in function in the called method accesses these objects while the called method is running. You can omit expressions, if appropriate, by including extra commas.

The receiver object is evaluated, followed by one or more expression arguments. The message name (in uppercase) and the resulting argument objects are then sent to the receiver object. The receiver object selects a method to be run based on the message name (see Classes and Inheritance), and runs the selected method with the specified argument objects. The receiver eventually returns, allowing processing to continue.

If the message term uses ~, the receiver method must return a result object. This object is included in the original expression as if the entire message term had been replaced by the name of a variable whose value is the returned object.

For example, the message POS is valid for strings, and you could code:

c="escape"
a="Position of 'e' is:" c~pos("e",3)
/* would set A to "Position of 'e' is: 6" */

If the message term uses ~~, the receiver method need not return a result object. Any result object is discarded, and the receiver object is included in the original expression in place of the message term.

For example, the messages INHERIT and SUBCLASS are valid for classes (see The Class Class) and, assuming the existence of the Persistent class, you could code:

account = .object~subclass("Account")~~inherit(.persistent)
/* would set ACCOUNT to the object returned by SUBCLASS, */
/* after sending that object the message INHERIT */

If the message term uses brackets, the message [ ] is sent to the receiver object. (The expressions within the brackets are available to the receiver object as arguments.) The effect is the same as for the corresponding ~ form of the message term. Thus, a[b] is the same as a~"[ ]"(b).

For example, the message [ ] is valid for arrays (see The Array Class) and you could code:

a = .array~of(10,20)
say "Second item is" a[2] /* Same as: a~at(2) */
/* or a~"[ ]"(2) */
/* Produces: "Second item is 20" */
A message can have a variable number of arguments. You need to specify only those required. For example, "ESCAPE"~POS("E") returns 1.

A colon (:) and symbol can follow the message name. In this case, the symbol must be the name of a variable (usually the special variable SUPER--see page SUPER) or an environment symbol (see Environment Symbols). The resulting value changes the usual method selection. For more information, see Changing the Search Order for Methods.

### 1.11.5. Message Sequences

The ~ and ~~ forms of message terms differ only in their treatment of the result object. Using ~ returns the result of the method. Using ~~ returns the object that received the message. Here is an example:

```rexx
team = .list~of("Bob","Mary")
team~insert("Jane")
team~insert("Joe")
team~insert("Steve")
say "First on the team is:" team~firstitem /* Bob */
say "Last on the team is:" team~lastitem /* Steve */
/* Do the same thing using -- */
team=.list~of("Bob","Mary")
/* Because -- returns the receiver of the message */
/* each INSERT message following returns the list */
/* object (after inserting the argument value). */
team~insert("Jane")~insert("Joe")~insert("Steve")
say "First on the team is:" team~firstitem /* Bob */
say "Last on the team is:" team~lastitem /* Steve */
```

Thus, you would use ~ when you want the returned result to be the receiver of the next message in the sequence.

### 1.12. Clauses and Instructions

Clauses can be subdivided into the following types:

- Null clauses
- Directives
- Labels
- Instructions
- Assignments
- Message instructions
- Keyword instructions
1.12.1. Null Clauses

A clause consisting only of whitespace characters, comments, or both is a null clause. It is completely ignored.

Note: A null clause is not an instruction; for example, putting an extra semicolon after the THEN or ELSE in an IF instruction is not equivalent to using a dummy instruction (as it would be in the C language). The NOP instruction is provided for this purpose.

1.12.2. Directives

A clause that begins with two colons is a directive. Directives are nonexecutable code and can start in any column. They divide a program into separate executable units (methods and routines) and supply information about the program or its executable units. Directives perform various functions, such as creating new Rexx classes (::CLASS directive) or defining a method (::METHOD directive). See Directives for more information about directives.

1.12.3. Labels

A clause that consists of a single symbol or string followed by a colon is a label. The colon in this context implies a semicolon (clause separator), so no semicolon is required.

The label’s name is taken from the string or symbol part of the label. If the label uses a symbol for the name, the label’s name is in uppercase. If a label uses a string, the name can contain mixed-case characters.

Labels identify the targets of CALL instructions, SIGNAL instructions, and internal function calls. Label searches for CALL, SIGNAL, and internal function calls are case-sensitive. Label-search targets specified as symbols cannot match labels with lowercase characters. Literal-string or computed-label searches can locate labels with lowercase characters.

Labels can be any number of successive clauses. Several labels can precede other clauses. Labels are treated as null clauses and can be traced selectively to aid debugging.

Duplicate labels are permitted, but control is only passed to the first of any duplicates in a program. The duplicate labels occurring later can be traced but cannot be used as a target of a CALL, SIGNAL, or function invocation.
1.12.4. Instructions

An instruction consists of one or more clauses describing some course of action for the language processor to take. Instructions can be assignments, message instructions, keyword instructions, or commands.

1.12.5. Assignments

A single clause of the form symbol=expression is an instruction known as an assignment. An assignment gives a (new) value to a variable. See Assignments and Symbols.

1.12.5.1. Extended Assignments

The character sequences +=, -=, *= /=, %=, //=, ||=, &=, |=, and &&= can be used to create extended assignments. These sequences combine an operation with the assignment. See Extended Assignments for more details.

1.12.5.2. Message Instructions

A message instruction is a single clause in the form of a message term (see Message Terms) or in the form messageterm=expression. A message is sent to an object, which responds by performing some action. See Message Instructions.

1.12.5.3. Keyword Instructions

A keyword instruction is one or more clauses, the first of which starts with a keyword that identifies the instruction. Keyword instructions control, for example, the external interfaces and the flow of control. Some keyword instructions can include nested instructions. In the following example, the DO construct (DO, the group of instructions that follow it, and its associated END keyword) is considered a single keyword instruction.

\[
\text{DO} \\
\quad \text{instruction} \\
\quad \text{instruction} \\
\quad \text{instruction} \\
\text{END}
\]

A subkeyword is a keyword that is reserved within the context of a particular instruction, for example, the symbols TO and WHILE in the DO instruction.

1.12.6. Commands

A command is a clause consisting of an expression only. The expression is evaluated and the result is passed as a command string to an external environment.
1.13. Assignments and Symbols

A variable is an object whose value can change during the running of a Rexx program. The process of changing the value of a variable is called assigning a new value to it. The value of a variable is a single object. Note that an object can be composed of other objects, such as an array or directory object.

You can assign a new value to a variable with the ARG, PARSE, PULL, or USE instructions, the VALUE built-in function, or the but the most common way of changing the value of a variable is the assignment instruction itself. Any clause in the form

```
symbol=value
```

is taken to be an assignment. The result of expression becomes the new value of the variable named by the symbol to the left of the equal sign.

**Example:**

/* Next line gives FRED the value "Frederic" */
Fred="Frederic"

The symbol naming the variable cannot begin with a digit (0-9) or a period.

You can use a symbol in an expression even if you have not assigned a value to it, because a symbol has a defined value at all times. A variable to which you have not assigned a value is uninitialized. Its value is the characters of the symbol itself, translated to uppercase (that is, lowercase a-z to uppercase A-Z).

However, if it is a compound symbol (described under Compound Symbols), its value is the derived name of the symbol.

**Example:**

/* If Freda has not yet been assigned a value, */
/* then next line gives FRED the value "FREDA" */
Fred=Freda

The meaning of a symbol in Rexx varies according to its context. As a term in an expression, a symbol belongs to one of the following groups: constant symbols, simple symbols, compound symbols, environment symbols, and stems. Constant symbols cannot be assigned new values. You can use simple symbols for variables where the name corresponds to a single value. You can use compound symbols and stems for more complex collections of variables although the collection classes might be preferable in many cases. See The Collection Classes.

1.13.1. Extended Assignments

The character sequences +=, -=, *= /=, %=, //=, ||=, &=, |=, and &&= can be used to create extended assignment instructions. An extended assignment combines a non-prefix operator with an assignment where the term on the left side of the assignment is also used as the left term of the operator. For example,

```
a += 1
```

is exactly equivalent to the instruction

```
a = a + 1
```
Extended assignments are processed identically to the longer form of the instruction.

1.13.2. Constant Symbols

A constant symbol starts with a digit (0-9) or a period.

You cannot change the value of a constant symbol. It is simply the string consisting of the characters of the symbol (that is, with any lowercase alphabetic characters translated to uppercase).

These are constant symbols:

77
827.53
.12345
12e5 /* Same as 12E5 */
3D
17E-3

Symbols where the first character is a period and the second character is alphabetic are environment symbols. Environment symbols may have a value other than the symbol name.

1.13.3. Simple Symbols

A simple symbol does not contain any periods and does not start with a digit (0-9).

By default, its value is the characters of the symbol (that is, translated to uppercase). If the symbol has been assigned a value, it names a variable and its value is the value of that variable.

These are simple symbols:

FRED
Whatagoodidea? /* Same as WHATAGOODIDEA? */
?12

1.13.4. Stems

A stem is a symbol that contains a single period as the last character of the name. It cannot start with a digit.

These are stems:

FRED.
A.

The value of a stem is always a Stem object. (See The Stem Class.) The stem variable’s Stem object is automatically created the first time you use the stem variable or a compound variable) containing the stem variable name. The Stem object’s assigned name is the name of the stem variable (with the characters translated to uppercase). If the stem variable has been assigned a value, or the Stem object has been given a default value, the assigned name override the default stem name. A reference to a stem variable will return the associate Stem object.
Chapter 1. Open Object Rexx General Concepts

When a stem is the target of an assignment, the action taken depends on the value being assigned. If the new value is a Stem object, the new Stem object will replace the Stem object that is currently associated with the stem variable. This can result in multiple stem variables referring to the same Stem object, effectively creating a variable alias.

**Example:**

```
hole. = "empty"
hole.19 = "full"
say hole.1 hole.mouse hole.19 /* Says "empty empty full" */

hole2. = hole. /* copies reference to hole. stem to hole2. */
say hole2.1 hole2.mouse hole2.19
/* Also says "empty empty full" */
```

If the new value is not a Stem object, a new Stem object is created and assigned to the stem variable, replacing the Stem object currently associated with the stem variable.

The new value assigned to the stem variable is given to the new Stem object as a default value. Following the assignment, a reference to any compound symbol with that stem variable returns the new value until another value is assigned to the stem, the Stem object, or the individual compound variable.

**Example:**

```
hole. = "empty"
hole.19 = "full"
say hole.1 hole.mouse hole.19 /* says "empty empty full" */
```

Thus, you can initialize an entire collection of compound variables to the same value.

You can pass stem collections as function, subroutine, or method arguments.

**Example:**

```
/* CALL RANDOMIZE count, stem. calls routine */
Randomize: Use Arg count, stem.
do i = 1 to count
   stem.i = random(1,100)
end
return
```

The USE ARG instruction functions as an assignment instruction. The variable STEM. in the example above is functionally equivalent to:

```
stem. = arg(2)
```

**Note:** USE ARG must be used to access the stem variable as a collection. PARSE and PARSE ARG will force the stem to be a string value.
Stems can also be returned as function, subroutine, or method results. The resulting return value is the Stem object associated with the stem variable.

**Example:**

```rexx
/* RANDOMIZE(count) calls routine */
Randomize: Use Arg count
do i = 1 to count
    stem.i = random(1,100)
end
return stem.
```

When a stem variable is used in an expression context, the stem variable reference returns the associated Stem object. The Stem object will forward many object messages to it’s default value. For example, the STRING method will return the Stem object’s default value’s string representation:

```rexx
total. = 0
say total. /* says "0" */
```

The [] method with no arguments will return the currently associated default value. variables can always be obtained by using the stem. However, this is not the same as using a compound variable whose derived name is the null string.

```rexx
total. = 0
null = ""
total.null = total.null + 5
say total.[] total.null /* says "0 5" */
```

You can use the DROP, EXPOSE, and PROCEDURE instructions to manipulate collections of variables, referred to by their stems. DROP FRED. assigns a new Stem object to the specified stem. (See DROP.) EXPOSE FRED. and PROCEDURE EXPOSE FRED. expose all possible variables with that stem (see EXPOSE and PROCEDURE).

The DO instruction can also iterate over all of the values assigned to a stem variable. See DO for more details.

**Notes:**

1. When the ARG, PARSE, PULL, or USE instruction, the VALUE built-in function, or the variable pool interface changes a variable, the effect is identical with an assignment.

2. Any clause that starts with a symbol and whose second token is (or starts with) an equal sign (=) is an assignment, rather than an expression (or a keyword instruction). This is not a restriction, because you can ensure that the clause is processed as a command, such as by putting a null string before the first name, or by enclosing the expression in parentheses.

   If you unintentionally use a Rexx keyword as the variable name in an assignment, this should not cause confusion. For example, the following clause is an assignment, not an ADDRESS instruction:
   ```rexx
   Address="10 Downing Street";
   ```

3. You can use the VAR function (see VAR) to test whether a symbol has been assigned a value. In addition, you can set SIGNAL ON NOVALUE to trap the use of any uninitialized variables (except when they are tails in compound variables or stem variables, which are always initialized with a Stem object when first used.)
1.13.5. Compound Symbols

A compound symbol contains at least one period and two other characters. It cannot start with a digit or a period, and if there is only one period it cannot be the last character.

The name begins with a stem (that part of the symbol up to and including the first period) and is followed by a tail, which are parts of the name (delimited by periods) that are constant symbols, simple symbols, or null. Note that you cannot use constant symbols with embedded signs (for example, 12.3E+5) after a stem; in this case the whole symbol would not be valid.

These are compound symbols:

FRED.3
Array.I.J
AMESSY..One.2.

Before the symbol is used, that is, at the time of reference, the language processor substitutes in the compound symbol the character string values of any simple symbols in the tail (I, J, and One in the examples), thus generating a new, derived tail. The value of a compound symbol is, by default, its the name of the Stem object associated with the stem variable concatenated to the derived tail or, if it has been used as the target of an assignment, the value of Stem element named by the derived tail.

The substitution in the symbol permits arbitrary indexing (subscripting) of collections of variables that have a common stem. Note that the values substituted can contain any characters (including periods and blanks). Substitution is done only once.

More formally, the derived name of a compound variable that is referenced by the symbol

s0.s1.s2. --- .sn

is given by

d0.v1.v2. --- .vn

where d0 is the name of the Stem object associated with the stem variable s0 and v1 to vn are the values of the constant or simple symbols s1 through sn. Any of the symbols s1 to sn can be null. The values v1 to vn can also be null and can contain any characters (including periods). Lowercase characters are not translated to uppercase, blanks are not removed, and periods have no special significance. There is no limit on the length of the evaluated name.

Some examples of simple and compound symbols follow in the form of a small extract from a Rexx program:

```rexx
a=3 /* assigns "3" to the variable A */
z=4 /* "4" to Z */
c="Fred" /* "Fred" to C */
a.z="Fred" /* "Fred" to A.4 */
a.fred=5 /* "5" to A.FRED */
a.c="Bill" /* "Bill" to A.Fred */
c.c=a.fred /* "5" to C.Fred */
y.a="Annie" /* "Annie" to Y.3.4 */
say a z c a.a a.z a.c c.a a.fred y.a.4 /* displays the string: */ /* "3 4 Fred A.3 Fred Bill C.3 5 Annie" */
```

You can use compound symbols to set up arrays and lists of variables in which the subscript is not necessarily numeric, thus offering a great scope for the creative programmer. A useful application is to set up an array in which the subscripts are taken from the value of one or more variables, producing a form of associative memory (content-addressable).

### 1.13.5.1. Evaluated Compound Variables

The value of a stem variable is always a Stem object (see The Stem Class for details). A Stem object is a type of collection that supports the [] and []= methods used by other collection classes. The [] method provides an alternate means of accessing compound variables that also allows embedded subexpressions.

**Examples:**

```rexx
a=3 /* assigns "3" to the variable A */
z=4 /* "4" to Z */
c="Fred" / /* "Fred" to C */
a.[z]="Fred" / /* "Fred" to A.4 */
a.[z+1]="Rick" / /* "Rick" to A.5 */
a.[fred]=5 / /* "5" to A.FRED */
a.[c]="Bill" / /* "Bill" to A.Fred */
c.[c]=a.fred / /* "5" to C.Fred */
y.[a,z]="Annie" / /* "Annie" to Y.3.4 */
say a z c a.[a] a.[z] a.[z+1]
a.[c] c.[a] a.[fred] y.[a,z]
/* displays the string: */
/* "3 4 Fred A.3 Fred Rick Bill C.3 5 Annie" */
```

### 1.13.6. Environment Symbols

An environment symbol starts with a period and has at least one other character. This character must not be a digit. By default the value of an environment symbol is the string consisting of the characters of the symbol (translated to uppercase). If the symbol identifies an object in the current environment, its value is the mapped object.

These are environment symbols:

- `.method` // A reference to the Rexx Method class
- `.true` // The Rexx "true" object. Has the value "1"
- `.xyz` // Normally the value .XYZ

When you use an environment symbol, the language processor performs a series of searches to see if the environment symbol has an assigned value. The search locations and their ordering are:

1. The directory of classes declared on ::CLASS directives (see ::CLASS) within the current program package or added to the current package using the addClass() method.
Chapter 1. Open Object Rexx General Concepts

2. The directory of PUBLIC classes declared on ::CLASS directives of other files included with a ::REQUIRES directive or added to the current Package instance using the addPackage() method.

3. The local environment directory specific to the current interpreter instance. The local environment includes process-specific objects such as the .INPUT and .OUTPUT objects. You can directly access the local environment directory by using the .LOCAL environment symbol. (See The Local Environment Object (.LOCAL).)

4. The global environment directory. The global environment includes all permanent Rexx objects such as the Rexx supplied classes (.ARRAY and so on) and constants such as .TRUE and .FALSE. You can directly access the global environment by using the .ENVIRONMENT environment symbol (see The Environment Object). Entries in the global environment directory can also be accessed via the VALUE built-in function (see VALUE) by using a null string for the selector argument.

5. Rexx defined symbols. Other simple environment symbols are reserved for use by Rexx built-in environment objects. The currently defined built-in objects are .RS, .LINE, .METHODS, .ROUTINES, and .CONTEXT.

If an entry is not found for an environment symbol, then the default character string value is used.

Note: You can place entries in both the .LOCAL and the .ENVIRONMENT directories for programs to use. To avoid conflicts with future Rexx defined entries, it is recommended that the entries that you place in either directory include at least one period in the entry name.

Example:

/* establish settings directory */
.local "setentry("MyProgram.settings", .directory"new")

1.14. Message Instructions

You can send a message to an object to perform an action, obtain a result, or both. You use a message instruction if the main purpose of the message is to perform an action. You use a message term (see Message Terms) if the main purpose of the message is to obtain a result.

A message instruction is a clause of the form:

```plaintext
>>-messageterm+-+-------------+--;------------------------------><
 +-=expression-+
```

If there is only a messageterm, the message is sent in exactly the same way as for a message term (see Message Terms). If the message yields a result object, it is assigned to the sender’s special variable RESULT. If you use the ~~ form of message term, the receiver object is used as the result. If there is no result object, the variable RESULT is dropped (becomes uninitialized). A message term using ~~ is sometimes referred to as a cascading message.

Example:
mytable\textasciitilde add(\texttt{"John"},123)

This sends the message ADD to the object MYTABLE. The ADD method need not return a result. If ADD returns a result, the result is assigned to the variable RESULT.

The equal sign (=) sets a value. If \texttt{=expression} follows the message term, a message is sent to the receiver object with an = concatenated to the end of the message name. The result of evaluating the expression is passed as the first argument of the message.

\textbf{Example:}

\begin{verbatim}
  person\textasciitilde age = 39  /* Same as person\textasciitilde "AGE\textasciitilde=(39) */
  table[i] = 5               /* Same as table\textasciitilde []\textasciitilde=(5,i) */
\end{verbatim}

The expressions are evaluated in the order in which the arguments are passed to the method. That is, the language processor evaluates the \texttt{=expression} first. Then it evaluates the argument expressions within any [] pairs from left to right.

The extended assignment form may also be used with messaging terms.

\textbf{Example:}

\begin{verbatim}
  table[i] += 1               -- Same as table[i] = table[i] + 1
\end{verbatim}

See \textit{Extended Assignments} for more details

\section*{1.15. Commands to External Environments}

Issuing commands to the surrounding environment is an integral part of Rexx.

\subsection*{1.15.1. Environment}

The base system for the language processor is assumed to include at least one environment for processing commands. An environment is selected by default on entry to a Rexx program. You can change the environment by using the ADDRESS instruction. You can find out the name of the current environment by using the ADDRESS built-in function. The underlying operating system defines environments external to the Rexx program. The environments selected depend on the caller. Normally the default environment is the used shell, mostly "CMD" on Windows systems and "bash" on Linux systems. If called from an editor that accepts subcommands from the language processor, the default environment can be that editor.

A Rexx program can issue commands—called \textit{subcommands}—to other application programs. For example, a Rexx program written for a text editor can inspect a file being edited, issue subcommands to make changes, test return codes to check that the subcommands have been processed as expected, and display messages to the user when appropriate.

An application that uses Rexx as a macro language must register its environment with the Rexx language processor. See the \textit{Open Object Rexx: Programming Guide} for a discussion of this mechanism.
1.15.2. Commands

To send a command to the currently addressed environment, use a clause of the form:

expression;

The expression (which must not be an expression that forms a valid message instruction—see Message Instructions) is evaluated, resulting in a character string value (which can be the null string), which is then prepared as appropriate and submitted to the environment specified by the current ADDRESS setting.

The environment then processes the command and returns control to the language processor after setting a return code. A return code is a string, typically a number, that returns some information about the command processed. A return code usually indicates if a command was successful but can also represent other information. The language processor places this return code in the Rexx special variable RC. See Special Variables.

In addition to setting a return code, the underlying system can also indicate to the language processor if an error or failure occurred. An error is a condition raised by a command to which a program that uses that command can respond. For example, a locate command to an editing system might report requested string not found as an error. A failure is a condition raised by a command to which a program that uses that command cannot respond, for example, a command that is not executable or cannot be found.

Errors and failures in commands can affect Rexx processing if a condition trap for ERROR or FAILURE is ON (see Conditions and Condition Traps). They can also cause the command to be traced if TRACE E or TRACE F is set. TRACE Normal is the same as TRACE F and is the default—see TRACE.

The .RS environment symbol can also be used to detect command failures and errors. When the command environment indicates that a command failure has occurred, the Rexx environment symbol .RS has the value -1. When a command error occurs, .RS has a value of 1. If the command did not have a FAILURE or ERROR condition, .RS is 0.

Here is an example of submitting a command. Where the default environment is Windows, the sequence:

fname = "CHESHIRE"
exten = "CAT"
"TYPE" fname "." exten

would result in passing the string TYPE CHESHIRE.CAT to the command processor, CMD.EXE. The simpler expression:

"TYPE CHESHIRE.CAT"

has the same effect.

On return, the return code placed in RC will have the value 0 if the file CHESHIRE.CAT were typed, or a nonzero value if the file could not be found in the current directory.

Note: Remember that the expression is evaluated before it is passed to the environment. Constant portions of the command should be specified as literal strings.

Windows Example:
**Chapter 1. Open Object Rexx General Concepts**

```plaintext
delete "*".lst /* not "multiplied by" */
var.003 = anyvalue
type "var.003" /* not a compound symbol */

w = any
dir"/\w" /* not "divided by ANY" */

**Linux Example:**

```plaintext
rm "*".lst /* not "multiplied by" */
var.003 = anyvalue
cat "var.003" /* not a compound symbol */

w = any
l0s "/\w" /* not "divided by ANY" */
```

Enclosing an entire message instruction in parentheses causes the message result to be used as a command. Any clause that is a message instruction is not treated as a command. Thus, for example, the clause

```
myfile~linein
```

causes the returned line to be assigned to the variable RESULT, not to be used as a command to an external environment, while

```
(myfile~linein)
```

would submit the return value from the linein method as a command to the external environment.

### 1.16. Using Rexx on Windows and Unix

Rexx programs can call other Rexx programs as external functions or subroutines with the `call` instruction.

If a program is called with the `call` instruction, the program runs in the same process as the calling program. If you call another program by a Rexx command, the program is executed in a new process and therefore does not share .environment, .local, or the Windows/Unix shell environment.

**Examples:**

```plaintext
call "other.REX" /* runs in the same process */
"rexx other.REX" /* runs in a new child process */
"start rexx other.REX" /* runs in a new detached process */
```

When Rexx programs call other Rexx programs as commands, the return code of the command is the exit value of the called program provided that this value is a whole number in the range -32768 to 32767. Otherwise, the exit value is ignored and the called program is given a return code of 0.
Chapter 2. Keyword Instructions

A *keyword instruction* is one or more clauses, the first of which starts with a keyword that identifies the instruction. Some keyword instructions affect the flow of control, while others provide services to the programmer. Some keyword instructions, like DO, can include nested instructions.

In the syntax diagrams on the following pages, symbols (words) in capitals denote keywords or subkeywords. Other words, such as *expression*, denote a collection of tokens as defined previously. Note, however, that the keywords and subkeywords are not case-dependent. The symbols `if`, `If`, and `iF` all have the same effect. Note also that you can usually omit most of the clause delimiters (;) shown because the end of a line implies them.

A keyword instruction is recognized *only* if its keyword is the first token in a clause and if the second token does not start with an equal (=) character (implying an assignment) or a colon (implying a label). The keywords ELSE, END, OTHERWISE, THEN, and WHEN are treated in the same way. Note that any clause that starts with a keyword defined by Rexx cannot be a command. Therefore,

```
arg(fred) rest
```

is an ARG keyword instruction, not a command that starts with a call to the ARG built-in function. A syntax error results if the keywords are not in their correct positions in a DO, IF, or SELECT instruction. The keyword THEN is also recognized in the body of an IF or WHEN clause. In other contexts, keywords are not reserved and can be used as labels or as the names of variables (though this is generally not recommended).

*Subkeywords* are reserved within the clauses of individual instructions. For example, the symbols VALUE and WITH are subkeywords in the ADDRESS and PARSE instructions, respectively. For details, see the description of each instruction.

Whitespace characters (blanks or horizontal tabs) adjacent to keywords separate the keyword from the subsequent token. One or more whitespace characters following VALUE are required to separate the expression from the subkeyword in the example following:

```
ADDRESS VALUE expression
```

However, no whitespace character is required after the VALUE subkeyword in the following example, although it would improve readability:

```
ADDRESS VALUE"ENVIR"||number
```

### 2.1. ADDRESS

```
ADDRESS---------------------------------;--------------------------<
  +environment--------------------++
  | +expression-++ |
  +---------------expression1------+
  ++VALUE-+
```
ADDRESS temporarily or permanently changes the destination of commands. Commands are strings sent to an external environment. You can send commands by specifying clauses consisting of only an expression or by using the ADDRESS instruction. (See Commands to External Environments.)

To send a single command to a specified environment, code an environment, a literal string or a single symbol, which is taken to be a constant, followed by an expression. The environment name is the name of an external procedure or process that can process commands. The expression is evaluated to produce a character string value, and this string is routed to the environment to be processed as a command. After execution of the command, environment is set back to its original state, thus temporarily changing the destination for a single command. The special variable RC and the environment symbol .RS are set and errors and failures in commands processed in this way are trapped or traced.

Windows Example:
ADDRESS CMD "DIR C:\CONFIG.SYS"

Linux Example:
ADDRESS "bash" "ls /usr/lib"

If you specify only environment, a lasting change of destination occurs: all commands (see Commands) that follow are routed to the specified command environment, until the next ADDRESS instruction is processed. The previously selected environment is saved.

Examples:
Assume that the environment for a Windows text editor is registered by the name EDIT:

address CMD
"DIR C:\AUTOEXEC.BAT"
if rc=0 then "COPY C:\AUTOEXEC.BAT C:\*.TMP"
address EDIT

Subsequent commands are passed to the editor until the next ADDRESS instruction.

Similarly, you can use the VALUE form to make a lasting change to the environment. Here expression1, which can be a variable name, is evaluated, and the resulting character string value forms the name of the environment. You can omit the subkeyword VALUE if expression1 does not begin with a literal string or symbol, that is, if it starts with a special character such as an operator character or parenthesis.

Example:
ADDRESS ("ENVIR"||number) /* Same as ADDRESS VALUE "ENVIR"||number */

With no arguments, commands are routed back to the environment that was selected before the previous change of the environment, and the current environment name is saved. After changing the environment, repeated execution of ADDRESS alone, therefore, switches the command destination between two environments. Using a null string for the environment name ("") is the same as using the default environment.

The two environment names are automatically saved across internal and external subroutine and function calls. See the CALL instruction (CALL) for more details.
Chapter 2. Keyword Instructions

The address setting is the currently selected environment name. You can retrieve the current address setting by using the ADDRESS built-in function. (See ADDRESS.) The Open Object Rexx: Programming Guide describes the creation of alternative subcommand environments.

2.2. ARG

```
>>>-ARG--+-template_list+-;-----------------------------------><
   +-template_list+-
ARG retrieves the argument strings provided to a program, internal routine, or method and assigns them to variables. It is a short form of the instruction:

>>>-PARSE UPPER ARG--+-template_list+-;-----------------------><
   +-template_list+-
```

The `template_list` can be a single template or list of templates separated by commas. Each template consists of one or more symbols separated by whitespace characters, patterns, or both.

The objects passed to the program, routine, or method are converted to string values and parsed into variables according to the rules described in Parsing.

The language processor converts the objects to strings and translates the strings to uppercase (that is, lowercase `a-z` to uppercase `A-Z`) before processing them. Use the PARSE ARG instruction if you do not want uppercase translation.

You can use the ARG and PARSE ARG instructions repeatedly on the same source objects (typically with different templates). The source objects do not change.

Example:

```rexx
/* String passed is "Easy Rider" */
Arg adjective noun .
/* Now: ADJECTIVE contains "EASY" */
/* NOUN contains "RIDER" */
```

If you expect more than one object to be available to the program or routine, you can use a comma in the parsing `template_list` so each template is selected in turn.

Example:

```rexx
/* Function is called by FRED("data X",1,5) */
Fred: Arg string, num1, num2
/* Now: STRING contains "DATA X" */
/* NUM1 contains "1" */
/* NUM2 contains "5" */
```

Notes:

1. The ARG built-in function can also retrieve or check the arguments. See ARG (Argument).
2. The USE ARG instruction (see USE) is an alternative way of retrieving arguments. USE ARG performs a direct, one-to-one assignment of argument objects to Rexx variables. You should use this when your program needs a direct reference to the argument object, without string conversion or parsing. ARG and PARSE ARG produce string values from the argument objects, and the language processor then parses the string values.

### 2.3. CALL

```
+---,-------------------+
| v                      |
|                       |
| CALL------name---------+
| (+expr)+              |
| (+expression)+        |
| OFF++++ANY-------------|
| ERROR------------------|
| FAILURE----------------|
| HALT--------------------|
| NOTREADY---------------|
| USER--usercondition+   |
| ON++++ANY--------------|
| ERROR------------------|
| NAME--trapname+        |
```

CALL calls a routine (if you specify `name`) or controls the trapping of certain conditions (if you specify ON or OFF).

To control trapping, you specify OFF or ON and the condition you want to trap. OFF turns off the specified condition trap. ON turns on the specified condition trap. All information on condition traps is contained in Conditions and Condition Traps.

To call a routine, specify `name`, which must be a literal string or symbol that is taken as a constant. The `usercondition` is a single symbol that is taken as a constant. The `trapname` is a symbol or string taken as a constant. The routine called can be:

**An internal routine**

A subroutine that is in the same program as the CALL instruction or function call that calls it. Internal routines are located using label instructions.

**A built-in routine**

A function that is defined as part of the Rexx language.

**An external routine**

A subroutine that is neither built-in nor a label within the same same program as the CALL instruction call that invokes it. See Search Order for details on the different types of external routines.
If *name* is a literal string (that is, specified in in quotation marks), the search for internal routines is bypassed, and only a built-in function or an external routine is called. Note that built-in function names are in uppercase. Therefore, a literal string call to a built-in function must also use uppercase characters.

You can also specify (*expr*), any valid expression enclosed in parentheses. The expression is evaluated before any of the argument expressions, and the value is the target of the CALL instruction. The language processor does not translate the expression value into uppercase, so the evaluated name must exactly match any label name or built-in function name. (See Labels for a description of label names.)

The called routine can optionally return a result. In this case, the CALL instruction is functionally identical with the clause:

```
+-,-,----------------+
  V
>>-result=name(--+-+----+--+----+)--;----------------------><
 +-expression-+
```

You can use any number of *expressions*, separated by commas. The expressions are evaluated from left to right and form the arguments during execution of the routine. Any ARG, PARSE ARG, or USE ARG instruction or ARG built-in function in the called routine accesses these objects while the called routine is running. You can omit expressions, if appropriate, by including extra commas.

The CALL then branches to the routine called *name*, using exactly the same mechanism as function calls. See Functions. The search order is as follows:

**Internal routines**

These are sequences of instructions inside the same program, starting at the label that matches *name* in the CALL instruction. If you specify the routine name in quotation marks, then an internal routine is not considered for that search order. The RETURN instruction completes the execution of an internal routine.

**Built-in routines**

These are routines built into the language processor for providing various functions. They always return an object that is the result of the routine. (See ARG (Argument).)

**Note:** You can call any built-in function as a subroutine. Any result is stored in RESULT. Simply specify CALL, the function name (with no parenthesis) and any arguments:

```ooRexx
call length "string" /* Same as length("string") */
say result /* Produces: 6 */
```

**External routines**

Users can write or use routines that are external to the language processor and the calling program. You can code an external routine in Rexx or in any language that supports the system-dependent interfaces. If the CALL instruction calls an external routine written in Rexx as a subroutine, you can retrieve any argument strings with the ARG, PARSE ARG, or USE ARG instructions or the ARG built-in function.

For more information on the search order, see Search Order.
Chapter 2. Keyword Instructions

During execution of an internal routine, all variables previously known are generally accessible. However, the PROCEDURE instruction can set up a local variables environment to protect the subroutine and caller from each other. The EXPOSE option on the PROCEDURE instruction can expose selected variables to a routine.

Calling an external program or routine defined with a ::ROUTINE directive is similar to calling an internal routine. The external routine, however, is an implicit PROCEDURE in that all the caller’s variables are always hidden. The status of internal values, for example NUMERIC settings, start with their defaults (rather than inheriting those of the caller). In addition, you can use EXIT to return from the routine.

When control reaches an internal routine, the line number of the CALL instruction is available in the variable SIGL (in the caller’s variable environment). This can be used as a debug aid because it is possible to find out how control reached a routine. Note that if the internal routine uses the PROCEDURE instruction, it needs to EXPOSE SIGL to get access to the line number of the CALL.

After the subroutine processed the RETURN instruction, control returns to the clause following the original CALL. If the RETURN instruction specified an expression, the variable RESULT is set to the value of that expression. Otherwise, the variable RESULT is dropped (becomes uninitialized).

An internal routine can include calls to other internal routines, as well as recursive calls to itself.

Example:

```rexx
/* Recursive subroutine execution... */
arg z
say z"! =" result
exit

factorial: procedure /* Calculate factorial by */
    arg n /* recursive invocation. */
    if n=0 then return 1
    call factorial n-1
    return result * n
```

During internal subroutine (and function) execution, all important pieces of information are automatically saved and then restored upon return from the routine. These are:

- **The status of loops and other structures**: Executing a SIGNAL within a subroutine is safe because loops and other structures that were active when the subroutine was called are not ended. However, those currently active within the subroutine are ended.

- **Trace action**: After a subroutine is debugged, you can insert a TRACE Off at the beginning of it without affecting the tracing of the caller. If you want to debug a subroutine, you can insert a TRACE Results at the start and tracing is automatically restored to the conditions at entry (for example, Off) upon return. Similarly, ? (interactive debug) is saved across routines.

- **NUMERIC settings**: The DIGITS, FUZZ, and FORM of arithmetic operations (in NUMERIC) are saved and then restored on return. A subroutine can, therefore, set the precision, for example, that it needs to use without affecting the caller.

- **ADDRESS settings**: The current and previous destinations for commands (see ADDRESS) are saved and then restored on return.
Chapter 2. Keyword Instructions

- **Condition traps**: CALL ON and SIGNAL ON are saved and then restored on return. This means that CALL ON, CALL OFF, SIGNAL ON, and SIGNAL OFF can be used in a subroutine without affecting the conditions the caller set up.

- **Condition information**: This information describes the state and origin of the current trapped condition. The CONDITION built-in function returns this information. See CONDITION.

- **.RS value**: The value of the .RS environment symbol. (See .RS.)

- **Elapsed-time clocks**: A subroutine inherits the elapsed-time clock from its caller (see TIME), but because the time clock is saved across routine calls, a subroutine or internal function can independently restart and use the clock without affecting its caller. For the same reason, a clock started within an internal routine is not available to the caller.

### 2.4. DO

```
>>>-DO---+-------------+--+---------------+--+-----------------+--;-->
       +LABEL--name-> +[ repetitor |+ + | conditional |+]
>>+-END--+--------+--;--------------------><
       | +-----------------+ | +--name--+
       | V | |
       +---instruction--;--++
```

**repetitor:***

```
|---+control1=expri++-------------+-----------------------------|
| | +TO--exprt++ ++BY--exprb++ ++FOR--exprf+ |
+-control2--OVER--collection-----------------------------+
+-FOREVER------------------------------------------------------+
+-exprrr--------------------------------------------------------+
```

**conditional:***

```
|---+WHILE--exprw+---------------------------------------------|
| ++UNTIL--expru+ |
```

DO groups instructions and optionally processes them repetitively. During repetitive execution, a control variable (control1 or control2) can be stepped through some range of values.

**Notes:**

1. The LABEL phrase, if used, must precede any repetitor or conditional.
2. The expr, expri, exprb, exprt, and exprf options, if present, are any expressions that evaluate to a number. The expr and exprf options are further restricted to result in a positive whole number or zero. If necessary, the numbers are rounded according to the setting of NUMERIC DIGITS.
3. The exprw or expru options, if present, can be any expression that evaluates to 1 or 0. This includes the list form of conditional expression supported by IF and WHEN, which is a list of expressions separated by ",.". Each subexpression must evaluate to either 0 or 1. The list of expressions is
evaluated left-to-right. Evaluation will stop with the first 0 result and 0 will be returned as the condition result. If all of the subexpressions evaluate to 1, then the condition result is also 1.

4. The TO, BY, and FOR phrases can be in any order, if used, and are evaluated in the order in which they are written.

5. The instruction can be any instruction, including assignments, commands, message instructions, and keyword instructions (including any of the more complex constructs such as IF, SELECT, and the DO instruction itself).

6. The subkeywords WHILE and UNTIL are reserved within a DO instruction in that they cannot be used as symbols in any of the expressions. Similarly, TO, BY, and FOR cannot be used in expr1, expr2, expr3, or expr4. FOREVER is also reserved, but only if it immediately follows the keyword DO and is not followed by an equal sign.

7. The exprb option defaults to 1, if relevant.

8. The collection can be any expression that evaluates to an object that supports a MAKEARRAY method. Array and List items return an array with the items in the appropriate order, as do Streams. Tables, Stems, Directories, etc. are not ordered so the items get placed in the array in no particular order.

For more information, refer to Using DO and LOOP.

### 2.5. DROP

```
+------------+
V |          |
>>-DROP----+-name---+-+--;-------------------------------------><
+(name)+
```

DROP "unassigns" variables, that is, restores them to their original uninitialized state. If `name` is not enclosed in parentheses, it identifies a variable you want to drop and must be a symbol that is a valid variable name, separated from any other `name` by one or more whitespace characters or comments.

If parentheses enclose a single `name`, then its value is used as a subsidiary list of variables to drop. Whitespace characters are not necessary inside or outside the parentheses, but you can add them if desired. This subsidiary list must follow the same rules as the original list, that is, be valid character strings separated by whitespace, except that no parentheses are allowed. The list need not contain any names—that is, it can be empty.

Variables are dropped from left to right. It is not an error to specify a name more than once or to drop a variable that is not known. If an exposed variable is named (see EXPOSE and PROCEDURE), then the original variable is dropped.

**Example:**

```
j=4
Drop a z.3 z.j
/* Drops the variables: A, Z.3, and Z.4 */
/* so that reference to them returns their names. */
```

Here, a variable name in parentheses is used as a subsidiary list.
Example:

```rexx
mylist="c d e"
drop (mylist) f
/* Drops the variables C, D, E, and F */
/* Does not drop MYLIST */
```

Specifying a stem (that is, a symbol that contains only one period as the last character) assigns the stem variable to a new, empty stem object.

Example:

```rexx
Drop z.
/* Assigns stem variable z. to a new empty stem object */
```

### 2.6. EXIT

EXIT leaves a program unconditionally. Optionally, EXIT returns a result object to the caller. The program is stopped immediately, even if an internal routine is being run. If no internal routine is active, RETURN (see RETURN) and EXIT are identical in their effect on the program running.

If you specify `expression`, it is evaluated and the object resulting from the evaluation is passed back to the caller when the program stops.

Example:

```rexx
j=3
Exit j*4
/* Would exit with the string "12" */
```

If you do not specify `expression`, no data is passed back to the caller. If the program was called as a function, this is detected as an error.

You can also use EXIT within a method. The method is stopped immediately, and the result object, if specified, is returned to the sender. If the method has previously issued a REPLY instruction (see REPLY), the EXIT instruction must not include a result expression.

**Notes:**

1. If the program was called through a command interface, an attempt is made to convert the returned value to a return code acceptable by the underlying operating system. The returned string must be a whole number whose value fits in a 16-bit signed integer (within the range -(2**15) to (2**15-1). If the conversion fails, no error is raised, and a return code of 0 is returned.

2. If you do not specify EXIT, EXIT is implied at the end of the program, but no result value is returned.

3. On Unix/Linux systems the returned value is limited to a numerical value between 0 and 255 (an unsigned byte).
Chapter 2. Keyword Instructions

2.7. EXPOSE

EXPOSE causes the object variables identified in `name` to be exposed to a method. References to exposed variables, including assigning and dropping, access variables in the current object’s variable pool. (An object variable pool is a collection of variables that is associated with an object rather than with any individual method.) Therefore, the values of existing variables are accessible, and any changes are persistent even after RETURN or EXIT from the method.

Any changes a method makes to an object variable pool are immediately visible to any other methods that share the same object variable scope. All other variables that a method uses are local to the method and are dropped on RETURN or EXIT. If an EXPOSE instruction is included, it must be the first instruction of the method.

If parentheses enclose a single `name`, then, after the variable `name` is exposed, the character string value of `name` is immediately used as a subsidiary list of variables. Whitespace characters are not necessary inside or outside the parentheses, but you can add them if desired. This subsidiary list must follow the same rules as the original list, that is, valid variable names separated by whitespace characters, except that no parentheses are allowed.

Variables are exposed in sequence from left to right. It is not an error to specify a name more than once, or to specify a name that has not been used as a variable.

Example:

```rexx
/* Example of exposing object variables */
myobj = .myclass~new
myobj~c
myobj~d /* Would display "Z is: 120" */
::class myclass /* The ::CLASS directive */
/* (see ::CLASS) */
::method c /* The ::METHOD directive */
/* (see ::METHOD) */
  expose z
  z = 100 /* Would assign 100 to the object variable z */
  return

::method d
  expose z
  z=z+20 /* Would add 20 to the same object variable z */
  say "Z is:" z
  return
```

You can expose an entire collection of compound variables (see Compound Symbols) by specifying their stem in the variable list or a subsidiary list. The variables are exposed for all operations.

Example:

```rexx
expose j k c. d.
```
2.8. FORWARD

```plaintext
>>>-FORWARD--+----------------+---------------+<
    +-CONTINUE-- +-ARGUMENTS--expra--+-
    |        |        |        |
    |        |        |        |
    +-ARRAY--(-----expri-----)--

Note: You can specify the options in any order.
```

FORWARD forwards the message that caused the currently active method to begin running. The FORWARD instruction can change parts of the forwarded message, such as the target object, the message name, the arguments, and the superclass override.

If you specify the TO option, the language processor evaluates `exprt` to produce a new target object for the forwarded message. The `exprt` is a literal string, constant symbol, or expression enclosed in parentheses. If you do not specify the TO option, the initial value of the Rexx special variable SELF is used.

If you specify the ARGUMENTS option, the language processor evaluates `expra` to produce an array object that supplies the set of arguments for the forwarded message. The `expra` can be a literal string, constant symbol, or expression enclosed in parentheses. The ARGUMENTS value must evaluate to a Rexx array object.

If you specify the ARRAY option, each `expri` is an expression (use commas to separate the expressions). The language processor evaluates the expression list to produce a set of arguments for the forwarded message. It is an error to use both the ARRAY and the ARGUMENTS options on the same FORWARD instruction.

If you specify neither ARGUMENTS nor ARRAY, the language processor uses the same arguments specified on the original method call.

If you specify the MESSAGE option, the `exprm` is a literal string, a constant symbol, or an expression enclosed in parentheses. If you specify an expression enclosed in parentheses, the language processor evaluates the expression to obtain its value. The uppercase character string value of the MESSAGE option is the name of the message that the FORWARD instruction issues.

If you do not specify MESSAGE, FORWARD uses the message name used to call the currently active method.
Chapter 2. Keyword Instructions

If you specify the CLASS option, the exprs is a literal string, a constant symbol, or an expression enclosed in parentheses. This is the class object used as a superclass specifier on the forwarded message.

If you do not specify CLASS, the message is forwarded without a superclass override.

If you do not specify the CONTINUE option, the language processor immediately exits the current method before forwarding the message. Results returned from the forwarded message are the return value from the original message that called the active method (the caller of the method that issued the FORWARD instruction). Any conditions the forwarded message raises are raised in the calling program (without raising a condition in the method issuing the FORWARD instruction).

If you specify the CONTINUE option, the current method does not exit and continues with the next instruction when the forwarded message completes. If the forwarded message returns a result, the language processor assigns it to the special variable RESULT. If the message does not return a result, the language processor drops (uninitializes) the variable RESULT.

The FORWARD instruction passes all or part of an existing message invocation to another method. For example, the FORWARD instruction can forward a message to a different target object, using the same message name and arguments.

Example:

::method substr
  forward to (self"string") /* Forward to the string value */

You can use FORWARD in a method to forward a message to a superclass’s methods, passing the same arguments. This is very common usage in object INIT methods.

Example:

::class savings subclass account
::method init
  expose type penalty
  forward class (super) continue /* Send to the superclass */
  type = "Savings" /* Now complete initialization */
  penalty = "1% for balance under 500"

In the preceding example, the CONTINUE option causes the FORWARD message to continue with the next instruction, rather than exiting the Savings class INIT method.
2.9. GUARD

GUARD controls a method’s exclusive access to an object.

GUARD ON acquires for an active method exclusive use of its object variable pool. This prevents other methods that also require exclusive use of the same variable pool from running on the same object. If another method has already acquired exclusive access, the GUARD instruction causes the issuing method to wait until the variable pool is available.

GUARD OFF releases exclusive use of the object variable pool. Other methods that require exclusive use of the same variable pool can begin running.

If you specify WHEN, the method delays running until the expression evaluates to 1 (true). If the expression evaluates to 0 (false), GUARD waits until another method assigns or drops an object variable (that is, a variable named on an EXPOSE instruction) used in the WHEN expression. When an object variable changes, GUARD reevaluates the WHEN expression. If the expression evaluates to true, the method resumes running. If the expression evaluates to false, GUARD resumes waiting.

Example:

```
::method c
    expose y
    if y>0 then
        return 1
    else
        return 0
::method d
    expose z
    guard on when z>0
    self~c /* Reevaluated when Z changes */
    say "Method D"
```

If you specify WHEN and the method has exclusive access to the object’s variable pool, then the exclusive access is released while GUARD is waiting for an object variable to change. Exclusive access is reacquired before the WHEN expression is evaluated. Once the WHEN expression evaluates to 1 (true), exclusive access is either retained (for GUARD ON WHEN) or released (for GUARD OFF WHEN), and the method resumes running.

Note: If the condition expression cannot be met, GUARD ON WHEN puts the program in a continuous wait condition. This can occur in particular when several activities run concurrently. See Guarded Methods for more information.
Chapter 2. Keyword Instructions

2.10. IF

```
>>>IF--expression-------THEN-------+instruction-----------+
  +--;+  +--;+

>-------------------------------------------------------------->
  +ELSE-------+instruction+
  +--;+
```

IF conditionally processes an instruction or group of instructions depending on the evaluation of the
expression. The expression is evaluated and must result in 0 or 1.

The instruction after the THEN is processed only if the result is 1 (true). If you specify an ELSE, the
instruction after ELSE is processed only if the result of the evaluation is 0 (false).

Example:

```
if answer="YES" then say "OK!"
else say "Why not?"
```

Remember that if the ELSE clause is on the same line as the last clause of the THEN part, you need a
semicolon before ELSE.

Example:

```
if answer="YES" then say "OK!"; else say "Why not?"
```

ELSE binds to the nearest IF at the same level. You can use the NOP instruction to eliminate errors and
possible confusion when IF constructs are nested, as in the following example.

Example:

```
If answer = "YES" Then
  If name = "FRED" Then
    say "OK, Fred."
  Else
    nop
  Else
    say "Why not?"
```

The expression may also be a list of expressions separated by ",". Each subexpression must evaluate to
either 0 or 1. The list of expressions is evaluated left-to-right. Evaluation will stop with the first 0 result
and 0 will be returned as the condition result. If all of the subexpressions evaluate to 1, then the condition
result is also 1.

Example:

```
If answer~datatype('w'), answer//2 = 0 Then
  say answer "is even"
Else
  say answer "is odd"
```

The example above is not the same as using the following

```
If answer~datatype('w') & answer//2 = 0 Then
```
say answer "is even"
Else
say answer "is odd"

The logical & operator will evaluate both terms of the operation, so the term "answer//2" will result in a syntax error if answer is a non-numeric value. With the list conditional form, evaluation will stop with the first false result, so the "answer//2" term will not be evaluated if the datatype test returns 0.

Notes:

1. The instruction can be any assignment, message instruction, command, or keyword instruction, including any of the more complex constructs such as DO, LOOP, SELECT, or the IF instruction itself. A null clause is not an instruction, so putting an extra semicolon (or label) after THEN or ELSE is not equivalent to putting a dummy instruction (as it would be in C). The NOP instruction is provided for this purpose.

2. The symbol THEN cannot be used within expression, because the keyword THEN is treated differently in that it need not start a clause. This allows the expression on the IF clause to be ended by THEN, without a semicolon (;) being required.

2.11. INTERPRET

>>>-INTERPRET--expression--;------------------------------------><

INTERPRET processes instructions that have been built dynamically by evaluating expression.

The expression is evaluated to produce a character string, and is then processed (interpreted) just as though the resulting string were a line inserted into the program and bracketed by a DO; and an END:

Any instructions (including INTERPRET instructions) are allowed, but note that constructions such as DO...END and SELECT...END must be complete. For example, a string of instructions being interpreted cannot contain a LEAVE or ITERATE instruction (valid only within a repetitive loop) unless it also contains the whole repetitive DO...END or LOOP...END construct.

A semicolon is implied at the end of the expression during execution, if one was not supplied.

Examples:

/* INTERPRET example */
data="FRED"
interpret data "= 4"
/* Builds the string "FRED = 4" and */
/* Processes: FRED = 4; */
/* Thus the variable FRED is set to "4" */

/* Another INTERPRET example */
data="do 3; say "Hello there!"; end"
interpret data /* Displays: */
/* Hello there! */
/* Hello there! */
/* Hello there! */
Chapter 2. Keyword Instructions

Notes:

1. Labels within the interpreted string are not permanent and are, therefore, an error.

2. Executing the INTERPRET instruction with TRACE R or TRACE I can be helpful in interpreting the results you get.

Example:

```rexx
/* Here is a small Rexx program. */
Trace Int
name="Kitty"
indirect="name"
interpret 'say "Hello" indirect"!"'
```

When this is run, you get the following trace:

```plaintext
3 *** name="Kitty"
   >L> "Kitty"
   >>> "Kitty"

4 *** indirect="name"
   >L> "name"
   >>> "name"

5 *** interpret 'say "Hello" indirect"!"
   >L> "say "Hello"
   >V> INDIRECT => "name"
   >O> " " => "say "Hello" name"
   >L> "!"
   >O> " " => "say "Hello" name!"
   >>> "say "Hello" name!"

5 *** say "Hello" name!"
   >L> "Hello"
   >V> NAME => "Kitty"
   >O> " " => "Hello Kitty"
   >L> "!"
   >O> " " => "Hello Kitty!"
   >>> "Hello Kitty!"
```

Hello Kitty!

Lines 3 and 4 set the variables used in line 5. Execution of line 5 then proceeds in two stages. First the string to be interpreted is built up, using a literal string, a variable (INDIRECT), and another literal string. The resulting pure character string is then interpreted, just as though it were actually part of the original program. Because it is a new clause, it is traced as such (the second *** trace flag under line 5) and is then processed. Again a literal string is concatenated to the value of a variable (NAME) and another literal, and the final result (Hello Kitty!) is then displayed.

3. For many purposes, you can use the VALUE function (see VALUE) instead of the INTERPRET instruction. The following line could, therefore, have replaced line 5 in the previous example:

```rexx
say "Hello" value(indirect)"!"
```

INTERPRET is usually required only in special cases, such as when two or more statements are to be interpreted together, or when an expression is to be evaluated dynamically.

4. You cannot use a directive (see Directives) within an INTERPRET instruction.
2.12. ITERATE

ITERATE alters the flow within a repetitive loop (that is, any DO construct other than that with a simple DO or a LOOP instruction).

Execution of the group of instructions stops, and control is passed to the DO or LOOP instruction just as though the END clause had been encountered. The control variable, if any, is incremented and tested, as usual, and the group of instructions is processed again, unless the DO or LOOP instruction ends the loop.

The name is a symbol, taken as a constant. If name is not specified, ITERATE continues with the current repetitive loop. If name is specified, it must be the name of the control variable or the LABEL name of a currently active loop, which can be the innermost, and this is the loop that is stepped. Any active loops inside the one selected for iteration are ended (as though by a LEAVE instruction).

Example:

```
loop label MyLabelName i=1 to 4 /* label set to 'MYLABELNAME' */
  if i=2 then iterate
  say i
end myLabelName
/* Displays the numbers:  
  1
  3
  4 */
```

Notes:

1. If specified, name must match the symbol naming the control variable or LABEL name in the DO or LOOP clause in all respects except the case. No substitution for compound variables is carried out when the comparison is made.

2. A loop is active if it is currently being processed. If a subroutine is called, or an INTERPRET instruction is processed, during the execution of a loop, the loop becomes inactive until the subroutine has returned or the INTERPRET instruction has completed. ITERATE cannot be used to continue with an inactive loop.

3. If more than one active loop uses the same name, ITERATE selects the innermost loop.

2.13. LEAVE

LEAVE causes an immediate exit from one or more repetitive loops or block instruction (simple DO or SELECT).

Processing of the group of instructions is ended, and control is passed to the instruction following the END clause, just as though the END clause had been encountered and the termination condition had
been met. However, on exit, the control variable, if any, contains the value it had when the LEAVE instruction was processed.

The \textit{name} is a symbol, taken as a constant. If \textit{name} is not specified, LEAVE ends the innermost active repetitive loop. If \textit{name} is specified, it must be the name of the control variable or LABEL name of a currently active LOOP, DO, or SELECT, which can be the innermost, and that block, and any active block inside it, are then ended. Control then passes to the clause following the END that matches the instruction of the selected block.

\textbf{Example:}

\begin{verbatim}
max=5
do label myDoBlock /* define a label 'MYDOBLOCK' */
   loop i=1 to max /* label defaults to control variable 'I' */
      if i = 2 then iterate i
      if i = 4 the leave myDoBlock
      say i
   end i
   say 'after looping' max 'times'
end myDoBlock
/* Displays the following
   1
   3
   after looping 4 times
*/
\end{verbatim}

\textbf{Notes:}

1. If specified, \textit{name} must match the symbol naming the control variable or LABEL name in the DO, LOOP, or SELECT clause in all respects except the case. No substitution for compound variables is carried out when the comparison is made.

2. A loop is active if it is currently being processed. If a subroutine is called, or an INTERPRET instruction is processed, during execution of a loop, the loop becomes inactive until the subroutine has returned or the INTERPRET instruction has completed. LEAVE cannot be used to end an inactive block.

3. If more than one active block uses the same control variable, LEAVE selects the innermost block.

\section*{2.14. LOOP}

\begin{verbatim}
---LOOP------------------------------------------+------------------------------------------+--;->
   +---LABEL--name--++| repetitor |++ | conditional |--++
---+--------------------+--------+--;-----------------------><
   | +----------------+ | +---name---+<
   | V | |
   | ---instruction--;+++ repetitor:
   | ---control1=expri--;------------------------------------------+--;->
\end{verbatim}
Chapter 2. Keyword Instructions

<table>
<thead>
<tr>
<th></th>
<th>-TO--exprt-+</th>
<th>-BY--exprb-+</th>
<th>-FOR--exprf-+</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>+control2--OVER--collection-------------------------------+</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>+FOREVER---------------------------------------------------+</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>+exprr----------------------------------------------------+</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

conditional:

<table>
<thead>
<tr>
<th></th>
<th>-WHILE--exprw-+---------------------------------------------</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-UNTIL--expru-+</td>
</tr>
</tbody>
</table>

LOOP groups instructions and processes them repetitively. During repetitive execution, a control variable (control1 or control2) can be stepped through some range of values.

Notes:

1. The LABEL phrase, if used, must precede any repetitor or conditional.

2. The exprr, expri, exprb, exprt, and exprf options, if present, are any expressions that evaluate to a number. The exprr and exprf options are further restricted to result in a positive whole number or zero. If necessary, the numbers are rounded according to the setting of NUMERIC DIGITS.

3. The exprw or expru options, if present, can be any expression that evaluates to 1 or 0. This includes the list form of conditional expression supported by IF and WHEN, which is a list of expressions separated by ",". Each subexpression must evaluate to either 0 or 1. The list of expressions is evaluated left-to-right. Evaluation will stop with the first 0 result and 0 will be returned as the condition result. If all of the subexpressions evaluate to 1, then the condition result is also 1.

4. The TO, BY, and FOR phrases can be in any order, if used, and are evaluated in the order in which they are written.

5. The instruction can be any instruction, including assignments, commands, message instructions, and keyword instructions (including any of the more complex constructs such as IF, SELECT, and the LOOP instruction itself).

6. The subkeywords WHILE and UNTIL are reserved within a LOOP instruction in that they cannot be used as symbols in any of the expressions. Similarly, TO, BY, and FOR cannot be used in expri, exprt, exprb, or exprf. FOREVER is also reserved, but only if it immediately follows the keyword LOOP and is not followed by an equal sign.

7. The exprb option defaults to 1, if relevant.

8. The collection can be any expression that evaluates to an object that supports a MAKEARRAY method. Array and List items return an array with the items in the appropriate order, as do Streams. Tables, Stems, Directories, etc. are not ordered so the items get placed in the array in no particular order.

For more information, refer to Using DO and LOOP.

2.15. NOP

>>-NOP;----------------------------------------------------------><

NOP is a dummy instruction that has no effect. It can be useful as the target of a THEN or ELSE clause.
Example:

Select
  when a=c then nop /* Do nothing */
  when a>c then say "A > C"
  otherwise say "A < C"
end

Note: Putting an extra semicolon instead of the NOP would merely insert a null clause, which would be ignored. The second WHEN clause would be seen as the first instruction expected after the THEN, and would, therefore, be treated as a syntax error. NOP is a true instruction, however, and is, therefore, a valid target for the THEN clause.

2.16. NUMERIC

**NUMERIC**

NUMERIC changes the way in which a program carries out arithmetic operations. The options of this instruction are described in detail in *Numbers and Arithmetic*.

**NUMERIC DIGITS**

controls the precision to which arithmetic operations and built-in functions are evaluated. If you omit expression1, the precision defaults to 9 digits, but can be overridden on a source-file basis using the ::OPTIONS directive. Otherwise, the character string value result of expression1 must evaluate to a positive whole number and must be larger than the current NUMERIC FUZZ setting.

There is no limit to the value for DIGITS (except the amount of storage available), but high precisions are likely to require a great amount of processing time. It is recommended that you use the default value whenever possible.

You can retrieve the current NUMERIC DIGITS setting with the DIGITS built-in function. See DIGITS.

**NUMERIC FORM**

controls the form of exponential notation for the result of arithmetic operations and built-in functions. This can be either SCIENTIFIC (in which case only one, nonzero digit appears before the decimal point) or ENGINEERING (in which case the power of 10 is always a multiple of 3). The default is SCIENTIFIC. The subkeywords SCIENTIFIC or ENGINEERING set the FORM directly, or it is taken from the character string result of evaluating the expression (expression2) that follows.
VALUE. The result in this case must be either SCIENTIFIC or ENGINEERING. You can omit the subkeyword VALUE if expression2 does not begin with a symbol or a literal string, that is, if it starts with a special character, such as an operator character or parenthesis. You can retrieve the current NUMERIC FORM setting with the FORM built-in function. See FORM.

**NUMERIC FUZZ**

controls how many digits, at full precision, are ignored during a numeric comparison operation. (See Numeric Comparisons.) If you omit expression3, the default is 0 digits. Otherwise, the character string value result of expression3 must evaluate to 0 or a positive whole number rounded, if necessary, according to the current NUMERIC DIGITS setting, and must be smaller than the current NUMERIC DIGITS setting.

NUMERIC FUZZ temporarily reduces the value of NUMERIC DIGITS by the NUMERIC FUZZ value during every numeric comparison. The numbers are subtracted under a precision of DIGITS minus FUZZ digits during the comparison and are then compared with 0.

You can retrieve the current NUMERIC FUZZ setting with the FUZZ built-in function. See FUZZ.

**Note:** The three numeric settings are automatically saved across internal subroutine and function calls. See the CALL instruction (CALL) for more details.

### 2.17. OPTIONS

```bash
>>>OPTIONS---+-----------+--;-------------------------------------><
   +-expression-+
```

The OPTIONS instruction is used to pass special requests to the language processor.

The expression is evaluated, and individual words in the result that are meaningful to the language processor will be obeyed. Options might control how the interpreter optimizes code, enforces standards, enables implementation-dependent features, etc.). Unrecognized words in the result are ignored, since they are assumed to be instructions for a different language processor.

Open Object Rexx does not recognize any option keywords.

### 2.18. PARSE

```bash
>>>PARSE---+------------------------+----------------------------------------->
   +-UPPER-  +-CASELESS-+
   +-LOWER-+

>>>ARG------------------------;--;-----------------------------------------><
   +-LINEIN-----------------+-template_list-+
   +-FULL-------------------+
   +-SOURCE----------------
```
Chapter 2. Keyword Instructions

PARSE assigns data from various sources to one or more variables according to the rules of parsing. (See Parsing.)

If you specify UPPER, the strings to be parsed are translated to uppercase before parsing. If you specify LOWER, the strings are translated to lowercase. Otherwise no translation takes place.

If you specify CASELESS, character string matches during parsing are made independent of the case. This means a letter in uppercase is equal to the same letter in lowercase.

The template_list can be a single template or list of templates separated by commas. Each template consists of one or more symbols separated by whitespace, patterns, or both.

Each template is applied to a single source string. Specifying several templates is not a syntax error, but only the PARSE ARG variant can supply more than one non-null source string. See Parsing Several Strings for information on parsing several source strings.

If you do not specify a template, no variables are set but the data is prepared for parsing, if necessary. Thus for PARSE PULL, a data string is removed from the current data queue, for PARSE LINEIN (and PARSE PULL if the queue is empty), a line is taken from the default input stream, and for PARSE VALUE, expression is evaluated. For PARSE VAR, the specified variable is accessed. If it does not have a value, the NOVALUE condition is raised, if it is enabled.

The following list describes the data for each variant of the PARSE instruction.

PARSE ARG

parses the strings passed to a program, routine, or method as input arguments. (See the ARG instruction in ARG for details and examples.)

Note: Parsing uses the string values of the argument objects. The USE ARG instruction provides direct access to argument objects. You can also retrieve or check the argument objects to a Rexx program, routine, or method with the ARG built-in function (see ARG (Argument)).

PARSE LINEIN

parses the next line of the default input stream. (See Input and Output Streams for a discussion of Rexx input and output.) PARSE LINEIN is a shorter form of the following instruction:

```plaintext
>>>PARSE VALUE LINEIN() WITH--+-template_list--
```

If no line is available, program execution usually pauses until a line is complete. Use PARSE LINEIN only when direct access to the character input stream is necessary. Use the PULL or

Note: You can specify UPPER and CASELESS or LOWER and CASELESS in either order.
Chapter 2. **Keyword Instructions**

PARSE PULL instructions for the usual line-by-line dialog with the user to maintain generality. PARSE LINEIN will not pull lines from the external data queue.

To check if any lines are available in the default input stream, use the built-in function LINES. See LINES (Lines Remaining) and LINEIN (Line Input).

### PARSE PULL

parses the next string of the external data queue. If the external data queue is empty, PARSE PULL reads a line of the default input stream (the user’s terminal), and the program pauses, if necessary, until a line is complete. You can add data to the head or tail of the queue by using the PUSH and QUEUE instructions, respectively. You can find the number of lines currently in the queue with the QUEUED built-in function. (See QUEUED.) The queue remains active as long as the language processor is active. Other programs in the system can alter the queue and use it to communicate with programs written in Rexx. See also the PULL instruction in PULL.

**Note:** PULL and PARSE PULL read the current data queue. If the queue is empty, they read the default input stream, .INPUT (typically, the keyboard).

### PARSE SOURCE

parses data describing the source of the program running. The language processor returns a string that does not change while the program is running.

The source string contains operating system name, followed by either COMMAND, FUNCTION, SUBROUTINE, or METHOD, depending on whether the program was called as a host command or from a function call in an expression or using the CALL instruction or as a method of an object. These two tokens are followed by the complete path specification of the program file.

The string parsed might, therefore, look like this:

- WindowsNT COMMAND C:\MYDIR\RexxTRY.CMD
- LINUX COMMAND /opt/orexx/bin/rexxtry.cmd

### PARSE VALUE

parses the data, a character string, that is the result of evaluating expression. If you specify no expression, the null string is used. Note that WITH is a subkeyword in this context and cannot be used as a symbol within expression.

Thus, for example:

```
PARSE VALUE time() WITH hours ":" mins ":" secs
```

gets the current time and splits it into its constituent parts.

### PARSE VAR name

parses the character string value of the variable name. The name must be a symbol that is valid as a variable name, which means it cannot start with a period or a digit. Note that the variable name is not changed unless it appears in the template, so that, for example:
Chapter 2. Keyword Instructions

PARSE VAR string word1 string
removes the first word from string, puts it in the variable word1, and assigns the remainder back to string.

PARSE UPPER VAR string word1 string
also translates the data from string to uppercase before it is parsed.

PARSE VERSION
parses information describing the language level and the date of the language processor. This information consists of five blank-delimited words:

• The string REXX-ooRexx
• The language level description, for example 6.03.
• Three tokens that describe the language processor release date in the same format as the default for the DATE built-in function (see DATE), for example, "27 Sep 2007".

2.19. PROCEDURE

PROCEDURE, within an internal routine (subroutine or function), protects the caller’s variables by making them unknown to the instructions that follow it. After a RETURN instruction is processed, the original variable environment is restored and any variables used in the routine (that were not exposed) are dropped. (An exposed variable is one belonging the caller of a routine that the PROCEDURE instruction has exposed. When the routine refers to, or alters, the variable, the original (caller’s) copy of the variable is used.) An internal routine need not include a PROCEDURE instruction. In this case the variables it is manipulating are those the caller owns. If the PROCEDURE instruction is used, it must be the first instruction processed after the CALL or function invocation; that is, it must be the first instruction following the label.

If you use the EXPOSE option, any variable specified by the name is exposed. Any reference to it (including setting and dropping) is made to the variables environment the caller owns. Hence, the values of existing variables are accessible, and any changes are persistent even on RETURN from the routine. If the name is not enclosed in parentheses, it identifies a variable you want to expose and must be a symbol that is a valid variable name, separated from any other name with one or more whitespace characters.

If parentheses enclose a single name, then, after the variable name is exposed, the character string value of name is immediately used as a subsidiary list of variables. Whitespace characters are not necessary inside or outside the parentheses, but you can add them if desired. This subsidiary list must follow the same rules as the original list, that is, valid variable names separated by whitespace characters, except that no parentheses are allowed.

Variables are exposed from left to right. It is not an error to specify a name more than once, or to specify a name that the caller has not used as a variable.
Any variables in the main program that are not exposed are still protected. Therefore, some of the caller’s variables can be made accessible and can be changed, or new variables can be created. All these changes are visible to the caller upon RETURN from the routine.

Example:

```rexx
/* This is the main Rexx program */
j=1; z.1="a"
call toft
say j k m /* Displays "1 7 M" */
exit

/* This is a subroutine */
toft: procedure expose j k z.j
    say j k z.j /* Displays "1 K a" */
k=7; m=3 /* Note: M is not exposed */
    return
```

Note that if \texttt{Z.J} in the EXPOSE list is placed before \texttt{J}, the caller’s value of \texttt{J} is not visible, so \texttt{Z.1} is not exposed.

The variables in a subsidiary list are also exposed from left to right.

Example:

```rexx
/* This is the main Rexx program */
j=1;k=6;m=9
a ="j k m"
call test
exit

/* This is a subroutine */
test: procedure expose (a) /* Exposes A, J, K, and M */
    say a j k m /* Displays "j k m 1 6 9" */
    return
```

You can use subsidiary lists to more easily expose a number of variables at a time or, with the VALUE built-in function, to manipulate dynamically named variables.

Example:

```rexx
/* This is the main Rexx program */
c=11; d=12; e=13
Showlist="c d" /* but not E */
call Playvars
say c d e f /* Displays "11 New 13 9" */
exit

/* This is a subroutine */
Playvars: procedure expose (showlist) f
    say word(showlist,2) /* Displays "d" */
    say value(word(showlist,2),"New") /* Displays "12" and sets new value */
    say value(word(showlist,2)) /* Displays "New" */
    e=8 /* E is not exposed */
    f=9 /* F was explicitly exposed */
```
Chapter 2. Keyword Instructions

return

Specifying a stem as name exposes this stem and all possible compound variables whose names begin with that stem. (See .)

Example:

/* This is the main Rexx program */
a.=11; i=13; j=15
i = i + 1
C.5 = "FRED"
call lucky7
say a. a.1 i j c. c.5
say "You should see 11 7 14 15 C. FRED"
exit

lucky7:Procedure Expose i j a. c.
   /* This exposes I, J, and all variables whose */
   /* names start with A. or C. */
   A.1="7" /* This sets A.1 in the caller-'s */
   /* environment, even if it did not */
   /* previously exist. */
   return

Note: Variables can be exposed through several generations of routines if they are included in all intermediate PROCEDURE instructions.

See the CALL instruction and function descriptions in CALL and Functions for details and examples of how routines are called.

2.20. PULL

**-PULL--+-template_list-+--;----------------------------------------------------------><
   +-template_list+-
PULL reads a string from the head of the external data queue or, if the external data queue is empty, from the standard input stream (typically the keyboard). (See Input and Output Streams for a discussion of Rexx input and output.) It is a short form of the following instruction:

**-PARSE UPPER PULL--+-template_list-+--;----------------------------------------------------------><
   +-template_list+-

The current head of the queue is read as one string. Without a template_list specified, no further action is taken and the string is thus effectively discarded. The template_list can be a single template or list of templates separated by commas, but PULL parses only one source string. Each template consists of one or more symbols separated by whitespace, patterns, or both.

If you specify several comma-separated templates, variables in templates other than the first one are assigned the null string. The string is translated to uppercase (that is, lowercase a-z to uppercase A-Z) and
then parsed into variables according to the rules described in Parsing. Use the PARSE PULL instruction if you do not desire uppercase translation.

**Note:** If the current data queue is empty, PULL reads from the standard input (typically, the keyboard). If there is a PULL from the standard input, the program waits for keyboard input with no prompt.

**Example:**

Say "Do you want to erase the file? Answer Yes or No:"
Pull answer .
if answer="NO" then say "The file will not be erased."

Here the dummy placeholder, a period (.), is used in the template to isolate the first word the user enters.

If the external data queue is empty, a line is read from the default input stream and the program pauses, if necessary, until a line is complete. (This is as though PARSE UPPER LINEIN had been processed. See PARSE LINEIN.)

The QUEUED built-in function (see QUEUED) returns the number of lines currently in the external data queue.

### 2.21. PUSH

```
>>>PUSH--------;------------------------------------><
+expression+
```

PUSH stacks the string resulting from the evaluation of expression LIFO (Last In, First Out) into the external data queue. (See Input and Output Streams for a discussion of Rexx input and output.)

If you do not specify expression, a null string is stacked.

**Example:**

```rexx
a="Fred"
push /* Puts a null line onto the queue */
push a 2 /* Puts "Fred 2" onto the queue */
```

The QUEUED built-in function (described in QUEUED) returns the number of lines currently in the external data queue.

### 2.22. QUEUE

```
>>>QUEUE--------;------------------------------------><
+expression+
```

ooRexx Reference Version 4.0.0
Chapter 2. Keyword Instructions

QUEUE appends the string resulting from expression to the tail of the external data queue. That is, it is added FIFO (First In, First Out). (See Input and Output Streams for a discussion of Rexx input and output.)

If you do not specify expression, a null string is queued.

Example:

```rexx
a="Toft"
queue a 2 /* Enqueues "Toft 2" */
queue /* Enqueues a null line behind the last */
```

The QUEUED built-in function (described in QUEUED) returns the number of lines currently in the external data queue.

2.23. RAISE

```
>>-RAISE---+---condition--------------------------+-| options |---<
    +-ERROR--errorcode------ ++|-- options |--+
    +-FAILURE--failurecode--
    +-SYNTAX--number--------
    +-USER--usercondition---
    +-PROPAGATE--------------
```

options:

```
|--------------------------------------------------------------------
    +-ADDITIONAL--expra------ ++-DESCRIPTION--exprd--
    |                   ++,------
    |                   V
    |                   +--ARRAY--(----exprri--+-)--
    ++|-- EXIT |--------+
>-----------------------------------------------------------------
    +--RETURN-----------++
        +--exprrr++
```

EXIT:

```
|--EXIT-----------------+---
    +-exprre--
```

Note: You can specify the options ADDITIONAL, ARRAY, DESCRIPTION, RETURN, and EXIT in any order. However, if you specify EXIT without exprer or RETURN without exprrr, it must appear last.

RAISE returns or exits from the currently running routine or method and raises a condition in the caller (for a routine) or sender (for a method). See Conditions and Condition Traps for details of the actions taken when conditions are raised. The RAISE instruction can raise all conditions that can be trapped.

If you specify condition, it is a single symbol that is taken as a constant.
If the ERROR or FAILURE condition is raised, you must supply the associated return code as `errorcode` or `failurecode`, respectively. These can be literal strings, constant symbols, or expressions enclosed in parentheses. If you specify an expression enclosed in parentheses, a subexpression, the language processor evaluates the expression to obtain its character string value.

If the SYNTAX condition is raised, you must supply the associated Rexx error number as `number`. This error `number` can be either a Rexx major error code or a Rexx detailed error code in the form `nn.nnn`. The `number` can be a literal string, a constant symbol, or an expression enclosed in parentheses. If you specify an expression enclosed in parentheses, the language processor evaluates the expression to obtain its character string value.

If a USER condition is raised, you must supply the associated user condition name as `usercondition`. This can be a literal string or a symbol that is taken as a constant.

If you specify the ADDITIONAL option, the language processor evaluates `expra` to produce an object that supplies additional object information associated with the condition. The `expra` can be a literal string, constant symbol, or expression enclosed in parentheses. The ADDITIONAL entry of the condition object and the “A” option of the CONDITION built-in function return this additional object information. For SYNTAX conditions, the ADDITIONAL value must evaluate to a single-dimension Rexx array object.

If you specify the ARRAY option, each `expri` is an expression (use commas to separate the expressions). The language processor evaluates the expression list to produce an array object that supplies additional object information associated with the condition. The ADDITIONAL entry of the condition object and the “A” option of the CONDITION built-in function return this additional object information as an array of values. It is an error to use both the ARRAY option and the ADDITIONAL option on the same RAISE instruction.

The content of `expra` or `expri` is used as the contents of the secondary error message produced for a condition.

If you specify neither ADDITIONAL nor ARRAY, there is no additional object information associated with the condition.

If you specify the DESCRIPTION option, the `exprd` can be a literal string, a constant symbol, or an expression enclosed in parentheses. If you specify an expression enclosed in parentheses, the language processor evaluates the expression to obtain its character string value. This is the description associated with the condition. The “D” option of the CONDITION built-in function and the DESCRIPTION entry of the condition object return this string.

If you do not specify DESCRIPTION, the language processor uses a null string as the descriptive string.

If you specify the RETURN or EXIT option, the language processor evaluates the expression `exprr` or `expre`, respectively, to produce a result object that is passed back to the caller or sender as if it were a RETURN or EXIT result. The `expre` or `exprr` is a literal string, constant symbol, or expression enclosed in parentheses. If you specify an expression enclosed in parentheses, the language processor evaluates the expression to obtain its character string value. If you do not specify `exprr` or `expre`, no result is passed back to the caller or sender. In either case, the effect is the same as that of the RETURN or EXIT instruction (see RETURN). Following the return or exit, the appropriate action is taken in the caller or sender (see Action Taken when a Condition Is Not Trapped). If specified, the result value can be obtained from the RESULT entry of the condition object.

Examples:

```
raise syntax 40 /* Raises syntax error 40 */
```
Chapter 2. Keyword Instructions

```plaintext
raise syntax 40.12 array (1, number) /* Raises syntax error 40, subcode 12 */
  /* Passing two substitution values */
raise syntax (errnum) /* Uses the value of the variable ERRNUM */
  /* as the syntax error number */
raise user badvalue /* Raises user condition BADVALUE */
```

If you specify PROPAGATE, and there is a currently trapped condition, this condition is raised again in the caller (for a routine) or sender (for a method). Any ADDITIONAL, DESCRIPTION, ARRAY, RETURN, or EXIT information specified on the RAISE instruction replaces the corresponding values for the currently trapped condition. A SYNTAX error occurs if no condition is currently trapped.

**Example:**

```plaintext
signal on syntax
  a = "xyz"
c = a+2    /* Raises the SYNTAX condition */

exit
syntax:
  raise propagate    /* Propagates SYNTAX information to caller */
```

### 2.24. REPLY

```plaintext
>>>REPLY--------;'-------------><
  +-expression+-
```

REPLY sends an early reply from a method to its caller. The method issuing REPLY returns control, and possibly a result, to its caller to the point from which the message was sent; meanwhile, the method issuing REPLY continues running on a newly created thread.

If you specify `expression`, it is evaluated and the object resulting from the evaluation is passed back. If you omit `expression`, no object is passed back.

Unlike RETURN or EXIT, the method issuing REPLY continues to run after the REPLY until it issues an EXIT or RETURN instruction. The EXIT or RETURN must not specify a result expression.

**Example:**

```plaintext
reply 42    /* Returns control and a result */
call tidyup    /* Can run in parallel with sender */
return
```

**Notes:**

1. You can use REPLY only in a method.
2. A method can execute only one REPLY instruction.
3. When the method issuing the REPLY instruction is the only active method on the current thread with exclusive access to the object’s variable pool, the method retains exclusive access on the new thread.
Chapter 2. Keyword Instructions

When other methods on the thread also have access, the method issuing the REPLY releases its access and reacquires the access on the new thread. This might force the method to wait until the original activity has released its access.

See Concurrency for a complete description of concurrency.

### 2.25. RETURN

```plaintext
>>-RETURN------------------;------------------------------->
   +-expression-+
```

RETURN returns control, and possibly a result, from a Rexx program, method, or routine to the point of its invocation.

If no internal routine (subroutine or function) is active, RETURN and EXIT are identical in their effect on the program that is run. (See EXIT.)

If called as a routine, `expression` (if any) is evaluated, control is passed back to the caller, and the Rexx special variable RESULT is set to the value of `expression`. If you omit `expression`, the special variable RESULT is dropped (becomes uninitialized). The various settings saved at the time of the CALL (for example, tracing and addresses) are also restored. (See CALL.)

If a function call is active, the action taken is identical, except that `expression` must be specified on the RETURN instruction. The result of `expression` is then used in the original expression at the point where the function was called. See the description of functions in Functions for more details.

If a method is processed, the language processor evaluates `expression` (if any) and returns control to the point from which the method's activating message was sent. If called as a term of an expression, `expression` is required. If called as a message instruction, `expression` is optional and is assigned to the Rexx special variable RESULT if a return `expression` is specified. If the method has previously issued a REPLY instruction, the RETURN instruction must not include a result `expression`.

If a PROCEDURE instruction was processed within an internal subroutine or internal function, all variables of the current generation are dropped (and those of the previous generation are exposed) after `expression` is evaluated and before the result is used or assigned to RESULT.

**Note:** If the RETURN statement causes the program to return to the operating system on a Unix/Linux system the value returned is limited to a numerical value between 0 and 255 (an unsigned byte). If no `expression` is supplied then the default value returned to the operating system is zero.

### 2.26. SAY

```plaintext
>>-SAY------------------;------------------------------->
   +-expression-+
```

SAY writes a line to the default output stream, which displays it to the user. However, the output destination can depend on the implementation. See Input and Output Streams for a discussion of Rexx
input and output. The string value of the expression result is written to the default character output stream. The resulting string can be of any length. If you omit expression, the null string is written.

The SAY instruction is a shorter form of the following instruction:

\[
\text{\texttt{CALL LINEOUT,+-expression+;+---}}
\]

except that:

- SAY does not affect the special variable RESULT.
- If you use SAY and omit expression, a null string is used.
- CALL LINEOUT can raise NOTREADY; SAY will not.

See LINEOUT (Line Output) for details of the LINEOUT function.

Example:

```rexx
data=100
Say data "divided by 4 =>" data/4
/* Displays: "100 divided by 4 => 25" */
```

Notes:

1. Data from the SAY instruction is sent to the default output stream (.OUTPUT). However, the standard rules for redirecting output apply to the SAY output.
2. The SAY instruction does not format data; the operating system and the hardware handle line wrapping. However, formatting is accomplished, the output data remains a single logical line.

### 2.27. SELECT

\[
\text{\texttt{SELECT+-expression+;+-}}
\]

SELECT conditionally calls one of several alternative instructions.

Each expression after a WHEN is evaluated in turn and must result in 0 or 1. If the result is 1, the instruction following the associated THEN (which can be a complex instruction such as IF, DO, LOOP,
or SELECT) is processed and control is then passed to the END. If the result is 0, control is passed to the next WHEN clause.

If none of the WHEN expressions evaluates to 1, control is passed to the instructions, if any, after OTHERWISE. In this situation, the absence of an OTHERWISE produces an error, however, you can omit the instruction list that follows OTHERWISE.

Example:

```
balance=100
check=50
balance = balance - check
Select
  when balance > 0 then
    say "Congratulations! You still have" balance "dollars left."
  when balance = 0 then do
    say "Warning, Balance is now zero! STOP all spending."
    say "You cut it close this month! Hope you do not have any"
    say "checks left outstanding."
  end
Otherwise do
  say "You have just overdrawn your account."
  say "Your balance now shows" balance "dollars."
  say "Oops! Hope the bank does not close your account."
end
/* Select */
```

The expression may also be a list of expressions separated by ",". Each subexpression must evaluate to either 0 or 1. The list of expressions is evaluated left-to-right. Evaluation will stop with the first 0 result and 0 will be returned as the condition result. If all of the subexpressions evaluate to 1, then the condition result is also 1.

Example:

```
select
  when answer~datatype('w'), answer//2 = 0 Then
    say answer "is even"
  when answer~datatype('w'), answer//2 = 1 Then
    say answer "is odd"
  otherwise
    say answer "is not a number"
end
```

The example above is not the same as using the following

```
select
  when answer~datatype('w') & answer//2 = 0 Then
    say answer "is even"
  when answer~datatype('w') & answer//2 = 1 Then
    say answer "is odd"
  otherwise
    say answer "is not a number"
end
```
Chapter 2. Keyword Instructions

The logical & operator will evaluate both terms of the operation, so the term "answer//2" will result in a syntax error if answer is a non-numeric value. With the list conditional form, evaluation will stop with the first false result, so the "answer//2" term will not be evaluated if the datatype test returns 0 (.false).

Notes:

1. The instruction can be any assignment, command, message instruction, or keyword instruction, including any of the more complex constructs, such as DO, LOOP, IF, or the SELECT instruction itself.
2. A null clause is not an instruction, so putting an extra semicolon (or label) after a THEN clause is not equivalent to putting a dummy instruction. The NOP instruction is provided for this purpose.
3. The symbol THEN cannot be used within expression, because the keyword THEN is treated differently in that it need not start a clause. This allows the expression on the WHEN clause to be ended by the THEN without a semicolon (;

2.28. SIGNAL

```
>>>SIGNAL--------------------------------------------|--|------>
>---+labelname----------------------------------+-;------>
   +---+expression-------------------------------+---+
   |   +VALUE+---------------------------------|
   +---+OFF---+ANY--------------------------+
       |   +ERROR-----------------------------|
       |   +FAILURE-----------------------------|
       |   +HALT-------------------------------|
       |   +LOSTDIGITS-------------------------|
       |   +NOMETHOD--------------------------|
       |   +NOSTRING--------------------------|
       |   +NOTREADY--------------------------|
       |   +NOVALUE---------------------------|
       |   +SYNTAX-----------------------------|
       |   +USER--usercondition+-              |
   +---+ON---+ANY--------------------------++----+
       |   +ERROR-----------------------------+   +NAME--trapname+|
       |   +FAILURE-----------------------------+|
       |   +HALT-------------------------------+|
       |   +LOSTDIGITS-------------------------+|
       |   +NOMETHOD--------------------------+|
       |   +NOSTRING--------------------------+|
       |   +NOTREADY--------------------------+|
       |   +NOVALUE---------------------------+|
       |   +SYNTAX-----------------------------+|
       |   +USER--usercondition+-              |
```

SIGNAL causes an unusual change in the flow of control (if you specify labelname or VALUE expression), or controls the trapping of certain conditions (if you specify ON or OFF).
To control trapping, you specify OFF or ON and the condition you want to trap. OFF turns off the specified condition trap. ON turns on the specified condition trap. All information on condition traps is contained in Conditions and Condition Traps.

To change the flow of control, a label name is derived from labelname or taken from the character string result of evaluating the expression after VALUE. The labelname you specify must be a literal string or symbol that is taken as a constant. If you specify a symbol for labelname, the search looks for a label with uppercase characters. If you specify a literal string, the search uses the literal string directly. You can locate label names with lowercase letters only if you specify the label as a literal string with the same case. Similarly, for SIGNAL VALUE, the lettercase of labelname must match exactly. You can omit the subkeyword VALUE if expression does not begin with a symbol or literal string, that is, if it starts with a special character, such as an operator character or parenthesis. All active pending DO, IF, SELECT, and INTERPRET instructions in the current routine are then ended and cannot be resumed. Control is then passed to the first label in the program that matches the given name, as though the search had started at the beginning of the program.

The labelname and usercondition are single symbols, which are taken as constants. The trapname is a string or symbol taken as a constant.

Example:

Signal fred; /* Transfer control to label FRED below */
....
....
Fred: say "Hi!"

If there are duplicates, control is always passed to the first occurrence of the label in the program.

When control reaches the specified label, the line number of the SIGNAL instruction is assigned to the special variable SIGL. This can aid debugging because you can use SIGL to determine the source of a transfer of control to a label.

### 2.29. TRACE

```
>>>TRACE<<<<+-----------------------+--;-------------------------><
| +number-- |                  |
| +Normal----+ |
+-----------------------+--------+
| +---------+ | +All--------+
| V        | | +Commands--+
+-----?-----+ +Error------+
 +Failure----+
 +Intermediates+
 +Labels------+
 +Off--------+
 +Results-----+
```

Or, alternatively:

```
>>>TRACE<<<<+----------------------+--;-------------------------><
| +string------+
```
Chapter 2. Keyword Instructions

TRACE controls the tracing action (that is, how much is displayed to the user) during the processing of a Rexx program. Tracing describes some or all of the clauses in a program, producing descriptions of clauses as they are processed. TRACE is mainly used for debugging. Its syntax is more concise than that of other Rexx instructions because TRACE is usually entered manually during interactive debugging. (This is a form of tracing in which the user can interact with the language processor while the program is running.)

**Note:** TRACE cannot be used in the Rexx macrospace. See Trace in Macrospace.

If specified, the *number* must be a whole number.

The *string* or *expression* evaluates to:

- A numeric option
- One of the valid prefix or alphabetic character (word) options described in Trace Alphabetic Character (Word) Options
- Null

The *symbol* is taken as a constant and is therefore:

- A numeric option
- One of the valid prefix or alphabetic character (word) options described in Alphabetic Character (Word) Options

The option that follows TRACE or the character string that is the result of evaluating *expression* determines the tracing action. You can omit the subkeyword VALUE if *expression* does not begin with a symbol or a literal string, that is, if it starts with a special character, such as an operator or parenthesis.

2.29.1. Trace Alphabetic Character (Word) Options

Although you can enter the word in full, only the first capitalized letter is needed; all following characters are ignored. That is why these are referred to as alphabetic character options.

TRACE actions correspond to the alphabetic character options as follows:

**All**

Traces (that is, displays) all clauses before execution.

**Commands**

Traces all commands before execution. If the command results in an error or failure (see Commands), tracing also displays the return code from the command.
Chapter 2. Keyword Instructions

Error
Traces any command resulting in an error or failure after execution (see Commands), together with the return code from the command.

Failure
Traces any command resulting in a failure after execution (see Commands), together with the return code from the command. This is the same as the Normal option.

Intermediates
Traces all clauses before execution. Also traces intermediate results during the evaluation of expressions and substituted names.

Labels
Traces only labels passed during execution. This is especially useful with debug mode, when the language processor pauses after each label. It also helps the user to note all internal subroutine calls and transfers of control because of the SIGNAL instruction.

Normal
Traces any failing command after execution, together with the return code from the command. This is the default setting.

For the default Windows command processor, an attempt to enter an unknown command raises a FAILURE condition. The CMD return code for an unknown command is 1. An attempt to enter a command in an unknown command environment also raises a FAILURE condition; in such a case, the variable RC is set to 30.

Off
Traces nothing and resets the special prefix option (described later) to OFF.

Results
Traces all clauses before execution. Displays the final results (in contrast with Intermediates option) of the expression evaluation. Also displays values assigned during PULL, ARG, PARSE, and USE instructions. This setting is recommended for general debugging.

2.29.2. Prefix Option

The prefix ? is valid alone or with one of the alphabetic character options. You can specify the prefix more than once, if desired. Each occurrence of a prefix on an instruction reverses the action of the previous prefix. The prefix must immediately precede the option (no intervening whitespace).

The prefix ? controls interactive debugging. During normal execution, a TRACE option with a prefix of ? causes interactive debugging to be switched on. (See Debugging Aids for full details of this facility.) When interactive debugging is on, interpretation pauses after most clauses that are traced. For example, the instruction TRACE ?E makes the language processor pause for input after executing any command that returns an error, that is, a nonzero return code or explicit setting of the error condition by the command handler.
Any TRACE instructions in the program being traced are ignored to ensure that you are not taken out of interactive debugging unexpectedly.

You can switch off interactive debugging in several ways:

- Entering `TRACE 0` turns off all tracing.
- Entering `TRACE` with no options restores the defaults—it turns off interactive debugging but continues tracing with TRACE Normal (which traces any failing command after execution).
- Entering `TRACE ?` turns off interactive debugging and continues tracing with the current option.
- Entering a TRACE instruction with a `?` prefix before the option turns off interactive debugging and continues tracing with the new option.

Using the `?` prefix, therefore, switches you in or out of interactive debugging. Because the language processor ignores any further TRACE statements in your program after you are in interactive debug mode, use `CALL TRACE "?"` to turn off interactive debugging.

### 2.29.3. Numeric Options

If interactive debugging is active and the option specified is a positive whole number (or an expression that evaluates to a positive whole number), that number indicates the number of debug pauses to be skipped. (See Debugging Aids for further information.) However, if the option is a negative whole number (or an expression that evaluates to a negative whole number), all tracing, including debug pauses, is temporarily inhibited for the specified number of clauses. For example, `TRACE -100` means that the next 100 clauses that would usually be traced are not displayed. After that, tracing resumes as before.

#### 2.29.3.1. Tracing Tips

- When a loop is traced, the DO clause itself is traced on every iteration of the loop.
- You can retrieve the trace actions currently in effect by using the TRACE built-in function (see TRACE).
- The trace output of commands traced before execution always contains the final value of the command, that is, the string passed to the environment, and the clause generating it.
- Trace actions are automatically saved across subroutine, function, and method calls. See CALL for more details.

#### 2.29.3.2. Example

One of the most common traces you will use is:

```
TRACE ?R
/* Interactive debugging is switched on if it was off, */
/* and tracing results of expressions begins. */
```
2.29.3.3. The Format of Trace Output

Every clause traced appears with automatic formatting (indentation) according to its logical depth of nesting, for example. Results, if requested, are indented by two extra spaces and are enclosed in double quotation marks so that leading and trailing whitespace characters are apparent. Any control codes in the data encoding (ASCII values less than "20"x) are replaced by a question mark (?) to avoid screen interference. Results other than strings appear in the string representation obtained by sending them a STRING message. The resulting string is enclosed in parentheses. The line number in the program precedes the first clause traced on any line. All lines displayed during tracing have a three-character prefix to identify the type of data being traced. These can be:

*-*
Identifies the source of a single clause, that is, the data actually in the program.

+++ Identifies a trace message. This can be the nonzero return code from a command, the prompt message when interactive debugging is entered, an indication of a syntax error when in interactive debugging.

>>> Identifies the result of an expression (for TRACE R) or the the value returned from a subroutine call, or a value evaluated by execution of a DO loop.

=> Identifies a variable assignment or a message assignment result. The trace message includes both the name of the assignment target and the assigned value. Assignment trace lines are displayed by assignment instructions, variable assigned via PARSE, ARG, PULL, or USE ARG, as well as control variable updates for DO and LOOP instructions.

>.> Identifies the value assigned to a placeholder during parsing (see The Period as a Placeholder).

The following prefixes are used only if TRACE Intermediates is in effect:

>ᴬ> Identifies a value used as a function, subroutine, or message argument.

>ᶜ> The data traced is the original name of the compound variable and the name of a compound variable, after the name has been replaced by the value of the variable but before the variable is used. If no value was assigned to the variable, the trace shows the variable in uppercase characters.

>ᴱ> The data traced is the name and value of an environment symbol.

>ᶠ> The data traced is the name and result of a function call.
Chapter 2. Keyword Instructions

The data traced is a literal (string, uninitialized variable, or constant symbol).

The data traced is the name and result of an object message.

The data traced is the name and result of an operation on two terms.

The data traced is the name and result of a prefix operation.

The data traced is the name and contents of a variable.

Note: The characters => indicate the value of a variable or the result of an operation.
The characters <= indicate a value assignment. The name to the left of the marker is the assignment topic. The data to the right of the marker is the assigned value.
The character ? could indicate a non-printable character in the output.

If no option is specified on a TRACE instruction, or if the result of evaluating the expression is null, the default tracing actions are restored. The defaults are TRACE N and interactive debugging (?) off.

Following a syntax error that SIGNAL ON SYNTAX does not trap, the clause in error is always traced.

2.30. USE

USE ARG retrieves the argument objects provided in a program, routine, function, or method and assigns them to variables or message term assignments.

Each name must be a valid variable name. The names are assigned from left to right. For each name you specify, the language processor assigns it a corresponding argument from the program, routine, function, or method call. If there is no corresponding argument, name is assigned the value of expr. If expr is not specified for the given argument, the variable name is dropped. If the assignment target is a messaging term, no action is taken for omitted arguments.

A USE ARG instruction can be processed repeatedly and it always accesses the same current argument data.
If `expr` is specified for an argument, the expression is evaluated to provide a default value for an argument when the corresponding argument does not exist. The default `expr` must be a literal string, a constant expression, or an expression enclosed in parentheses.

The `names` may be any valid symbol or message term which can appear on the left side of an assignment statement (See Assignments and Symbols).

The STRICT options imposes additional constraints on argument processing. The number of arguments must match the number of `names`, otherwise an error is raised. An argument may be considered optional if `expr` has been specified for the argument.

The ellipsis ("...") can be given in place of the last variable in the USE STRICT ARG statement and indicates that more arguments may follow. It allows defining a minimum amount of arguments that must be supplied or for which there are default values defined and that may be followed optionally by any additional arguments.

**Example:**

```rexx
/* USE Example */
/* FRED("Ogof X",1,5) calls function */
Fred: use arg string, num1, num2

/* Now: STRING contains "Ogof X" */
/* NUM1 contains "1" */
/* NUM2 contains "5" */

/* Another example, shows how to pass non-string arguments with USE ARG */
/* Pass a stem and an array to a routine to modify one element of each */
stem.1 = "Value"
array = .array~of("Item")
say "Before subroutine:" stem.1 array[1] /* Shows "Value Item" */
Call Change_First stem., array
say "After subroutine:" stem.1 array[1] /* Shows "NewValue NewItem" */
Exit

Change_First: Procedure
  Use Arg substem., subarray
  substem.1 = "NewValue"
  subarray[1] = "NewItem"
  Return

/* USE STRICT Example */
/* FRED("Ogof X",1) calls function */
Fred: use strict arg string, num1, num2=4

/* Now: STRING contains "Ogof X" */
/* NUM1 contains "1" */
/* NUM2 contains "4" */
```

In the above example, a call to the function FRED may have either 2 or 3 arguments. The STRICT keyword on the USE instruction will raise a syntax error for any other combination of arguments.

**Example:**

```rexx
call test "one"
```
call test "one", "two"
call test "one", "two", "three"
call test "one", , "three", "four", "five"
exit

test: procedure /* a minimum of one argument must be supplied */
  use strict arg v1, v2="zwei", ...
  say "There are ["arg()"] argument(s); v1,v2=["v1","v2"]"
  do i=3 to arg()
    say " arg #" i="[arg(i)]"
  end
  say "--"
  return

Output:

There are [1] argument(s); v1,v2=[one,zwei]
--
There are [2] argument(s); v1,v2=[one,two]
--
There are [3] argument(s); v1,v2=[one,two]
  arg # 3=[three]
--
There are [5] argument(s); v1,v2=[one,zwei]
  arg # 3=[three]
  arg # 4=[four]
  arg # 5=[five]
--

The assignment targets may be any term that can be on the left side of an assignment statement. For example,

expose myArray myDirectory
use arg myArray[1], myDirectory~name

would be equivalent to

myArray[1] = arg(1)
myDirectory~name = arg(2)

You can retrieve or check the arguments by using the ARG built-in function (see ARG (Argument)). The ARG and PARSE ARG instructions are alternative ways of retrieving arguments. ARG and PARSE ARG access the string values of arguments. USE ARG performs a direct, one-to-one assignment of arguments. This is preferable when you need direct access to an argument, without translation or parsing. USE ARG also allows access to both string and non-string argument objects; ARG and PARSE ARG convert the arguments to values before parsing.
Chapter 3. Directives

A Rexx program contains one or more executable code units. Directive instructions separate these executable units. A directive begins with a double colon (::) and is a nonexecutable instruction. For example, it cannot appear in a string for the INTERPRET instruction to be interpreted. The first directive instruction in a program marks the end of the main executable section of the program.

For a program containing directives, all directives are processed first to set up the program’s classes, methods, and routines. Then any program code in the main code unit (preceding the first directive) is processed. This code can use any classes, methods, and routines that the directives established.

3.1. ::ATTRIBUTE

The ::ATTRIBUTE directive creates attribute methods and defines the method properties.

```
>>> ::ATTRIBUTE --name-- +-----+-------+-------+------------------------->
    ++GET++    ++CLASS++
    ++SET++

    ++PUBLIC++    ++GUARDED++    ++UNPROTECTED++
>------------------------------------------------------------------------>
    ++PRIVATE++    ++UNGUARDED++    ++PROTECTED++

>------------------------------------------------------------------------<<
    ++EXTERNAL-spec++
```

The ::ATTRIBUTE directive creates accessor methods for object instance variables. An accessor method allows an object instance variable to be retrieved or assigned a value. ::ATTRIBUTE can create an attribute getter method, a setter method, or the getter/setter pair.

The `name` is a literal string or a symbol that is taken as a constant. The `name` must also be a valid Rexx variable name. The ::ATTRIBUTE directive creates methods in the class specified in the most recent ::CLASS directive. If no ::CLASS directive precedes an ::ATTRIBUTE directive, the attribute methods are not associated with a class but are accessible to the main (executable) part of a program through the .METHODS built-in object. Only one ::ATTRIBUTE directive can appear for any method name not associated with a class. See .METHODS for more details.

If you do not specify either SET or GET, ::ATTRIBUTE will create two attribute methods with the names `name` and `name=`. These are the methods for getting and setting an attribute. These generated methods are equivalent to the following code sequences:

```
::method "NAME=" /* attribute set method */
expose name    /* establish direct access to object variable (attribute) */
use arg name   /* retrieve argument and assign it to the object variable */

::method name  /* attribute get method */
expose name    /* establish direct access to object variable (attribute) */
return name    /* return object’s current value */
```
Both methods will be created with the same method properties (for example, PRIVATE, GUARDED, etc.). If GET or SET are not specified, the pair of methods will be automatically generated. In that case, there is no method code body following the directive, so another directive (or the end of the program) must follow the ::ATTRIBUTE directive.

If GET or SET is specified, only the single get or set attribute method is generated. Specifying separate GET or SET ::ATTRIBUTE directives allows the methods to be created with different properties. For example, the sequence:

::attribute name get
::attribute name set private

will create a NAME method with PUBLIC access and a NAME= method with PRIVATE access.

The GET and SET options may also be used to override the default method body generated for the attribute. This is frequently used so the SET attribute method can perform new value validation.

::attribute size get
::attribute size set
   expose size  /* establish direct access to object variable (attribute) */
   use arg value  /* retrieve argument */
   if datatype(value, "Whole") = .false | value < 0 then
     raise syntax 93.906 array ("size", value)
   size=value

If you specify the CLASS option, the created methods are class methods. See Objects and Classes. The attribute methods are associated with the class specified on the most recent ::CLASS directive. The ::ATTRIBUTE must be preceded by a ::CLASS directive if CLASS is specified.

If the EXTERNAL option is specified, then spec identifies a method in an external native library that will be invoked as the named method. The spec is a literal string containing a series of whitespace delimited tokens defining the external method. The first token must be the word LIBRARY, which indicates the method resides in a native library of the type allowed on a ::REQUIRES directive. The second token must identify the name of the external library. The external library is located using platform-specific mechanisms for loading libraries. For Unix-based systems, the library name is case-sensitive. The third token is optional and specifies the name of the method within the library package. If not specified, the ::METHOD name is used. The target package method name is case insensitive.

If the SET or GET option is not specified with the EXTERNAL option, then two method objects need to be created. The target method name is appended to the string "GET" to derive the name of the getter attribute method. To generate the setter attribute method, the name is appended to the string "SET". If GET or SET is specified and the method name is not specified within spec, then the target library method name is generated by concatenating name with "GET" or "SET" as appropriate. If the method name is specified in spec and GET or SET is specified, the spec name will be used unchanged.

Example:

-- maps "NAME" method to "GETNAME" and -- "NAME=" to "SETNAME"
::ATTRIBUTE name EXTERNAL "LIBRARY mylib"
-- maps "ADDRESS" method to "GETADDRESS"
::ATTRIBUTE address GET EXTERNAL "LIBRARY mylib"
-- maps "ADDRESS=" method to "setHomeAddress"
::ATTRIBUTE address SET EXTERNAL "LIBRARY mylib setHomeAddress"
Notes:

1. You can specify all options in any order.

2. If you specify the PRIVATE option, the created methods are private methods. Private methods have restricted access rules on how they can be invoked. See Public versus Private Methods for details of how private methods can be used. If you omit the PRIVATE option or specify PUBLIC, the method is a public method that any sender can activate.

3. If you specify the UNGUARDED option, the methods can be called while other methods are active on the same object. If you do not specify UNGUARDED, the method requires exclusive use of the object variable pool; it can run only if no other method that requires exclusive use of the object variable pool is active on the same object.

4. If you specify the PROTECTED option, the method methods are protected methods. (See The Security Manager for more information.) If you omit the PROTECTED option or specify UNPROTECTED, the methods are not protected.

5. It is an error to specify ::ATTRIBUTE more than once within a class definition that creates a duplicate get or set method.

### 3.2. ::CLASS

The ::CLASS directive causes the interpreter to create a Rexx class.

```apl
>>-::CLASS--classname--+-+----------------------+-------------------+--METACLASS--metaclass+++
   +-METACLASS--metaclass++
   +-SUBCLASS--Object---+-PRIVATE-++
   >+-+------------------++------------------++-PRIVATE---++
   +-MIXINCLASS--mclass++ +-PUBLIC---++-INHERIT--iclasses++
   +-SUBCLASS--sclass---++
```

The ::CLASS directive creates a Rexx class named *classname*. The *classname* is a literal string or symbol that is taken as a constant. The created class is available to programs through the Rexx environment symbol `.classname`. The *classname* acquires all methods defined by subsequent ::METHOD directives until the end of the program or another ::CLASS directive is found. Only null clauses (comments or blank lines) can appear between a ::CLASS directive and any following directive instruction or the end of the program. Only one ::CLASS directive can appear for *classname* in a program.

If you specify the METACLASS option, the instance methods of the *metaclass* class become class methods of the *classname* class. (See Objects and Classes.) The *metaclass* and *classname* are literal strings or symbols that are taken as constants. In the search order for methods, the metaclass methods precede inherited class methods and follow any class methods defined by ::METHOD directives with the CLASS option.

If you specify the PUBLIC option, the class is visible beyond its containing Rexx program to any other program that references this program with a ::REQUIRES directive. (See ::REQUIRES.) If you do not specify the PUBLIC option, the class is visible only within its containing Rexx program. All public classes defined within a program are used before PUBLIC classes created with the same name.
If you specify the SUBCLASS option, the class becomes a subclass of the class `sclass` for inheritance of instance and class methods. The `sclass` is a literal string or symbol that is taken as a constant.

If you specify the MIXINCLASS option, the class becomes a subclass of the class `mclass` for inheritance of instance and class methods. You can add the new class instance and class methods to existing classes by using the INHERIT option on a `::CLASS` directive or by sending an INHERIT message to an existing class. If you specify neither the SUBCLASS nor the MIXINCLASS option, the class becomes a non-mixin subclass of the Object class.

If you specify the INHERIT option, the class inherits instance methods and class methods from the classes `iclasses` in their order of appearance (leftmost first). This is equivalent to sending a series of INHERIT messages to the class object, with each INHERIT message (except the first) specifying the preceding class in `iclasses` as the classpos argument. (See INHERIT.) As with the INHERIT message, each of the classes in `iclasses` must be a mixin class. The `iclasses` is a whitespace-separated list of literal strings or symbols that are taken as constants. If you omit the INHERIT option, the class inherits only from `sclass`.

**Example:**

```rexx
::class rectangle
::method area /* defined for the RECTANGLE class */
   expose width height
   return width*height

::class triangle
::method area /* defined for the TRIANGLE class */
   expose width height
   return width*height/2
```

The `::CLASS` directives in a program are processed in the order in which they appear. If a `::CLASS` directive has a dependency on `::CLASS` directives that appear later in the program, processing of the directive is deferred until all of the class’s dependencies have been processed.

**Example:**

```rexx
::class savings subclass account /* requires the ACCOUNT class */
::method type
   return "a Savings Account"

::class account
::method type
   return "an Account"
```

The Savings class in the preceding example is not created until the Account class that appears later in the program has been created.

**Notes:**

1. You can specify the options METACLASS, MIXINCLASS, SUBCLASS, and PUBLIC in any order.
2. If you specify INHERIT, it must be the last option.
3.3. ::CONSTANT

The ::CONSTANT directive creates methods that return constant values for a class and its instances.

```ooRexx
::CONSTANT--name--value--
```

A ::CONSTANT directive defines a method that returns a constant value. This is useful for creating named constants associated with a class.

The `name` is a literal string or a symbol that is taken as a constant. A method of the given name is created as both an instance method and a class method of the most recent ::CLASS directive. A ::CLASS directive is not required before a ::CONSTANT directive. If no ::CLASS directive precedes ::CONSTANT, a single constant method is created that is not associated with a class but is accessible to the main (executable) part of a program through the .METHODS built-in object. Only one ::CONSTANT directive can appear for any method name not associated with a class. See .METHODS for more details.

The methods created by a ::CONSTANT directive are UNGUARDED and will have a return result that is specified by `value`. The constant value must be a single literal string or symbol that is taken as a constant. Also permitted is the single character "-" or "+" followed by a literal string or symbol that is a valid number. Here are some examples of valid constants:

```ooRexx
::class MathConstants public
::constant pi 3.1415926 ::constant author "Isaac Asimov"
::constant absolute_zero -273.15
```

A ::CONSTANT directive is a shorthand syntax for creating constants associated with a class. The created name constant can be accessed using either the class object or an instance of the class itself. For example:

```ooRexx
say "Pi is" .MathConstants~pi -- displays "Pi is 3.1415926"
instance = .MathConstants~new
say "Pi is" instance~pi -- also displays "Pi is 3.1415926"
```

3.4. ::METHOD

The ::METHOD directive creates a method object and defines the method attributes.

```ooRexx
```

```ooRexx
```
Chapter 3. Directives

A ::METHOD directive creates method objects that may be associated with a class instance. The created method may be from Rexx code, mapped to method in an external native library, or automatically generated. The type of method is determined by the combination of options specified.

The methodname is a literal string or a symbol that is taken as a constant. The method is defined as methodname in the class specified in the most recent ::CLASS directive. Only one ::METHOD directive can appear for any methodname in a class.

A ::CLASS directive is not required before a ::METHOD directive. If no ::CLASS directive precedes ::METHOD, the method is not associated with a class but is accessible to the main (executable) part of a program through the .METHODS built-in object. Only one ::METHOD directive can appear for any method name not associated with a class. See .METHODS for more details.

If you specify the CLASS option, the method is a class method. See Objects and Classes. The method is associated with the class specified on the most recent ::CLASS directive. The ::METHOD directive must follow a ::CLASS directive when the CLASS option is used.

If ABSTRACT, ATTRIBUTE, or EXTERNAL is not specified, the ::METHOD directive starts a section of method code which is ended by another directive or the end of the program. The ::METHOD is not included in the source of the created METHOD object.

Example:

```plaintext
r = .rectangle~new(20,10)
say "Area is" r~area /* Produces "Area is 200" */
::class rectangle
    ::method area /* defined for the RECTANGLE class */
        expose width height
        return width*height
    ::method init
        expose width height
        use arg width, height
    ::method perimeter
        expose width height
        return (width+height)*2
```

If you specify the ATTRIBUTE option, method variable accessor methods are created. In addition to generating a method named methodname, another method named methodname= is created. The first method returns the value of object instance variable that matches the method name. The second method assigns a new value to the object instance variable.

For example, the directive

```plaintext
::method name attribute
```

creates two methods, NAME and NAME=. The NAME and NAME= methods are equivalent to the following code sequences:

```plaintext
::method "NAME="
    expose name
    use arg name
```
::method name
     expose name
     return name

If you specify the ABSTRACT option, the method creates an ABSTRACT method placeholder. ABSTRACT methods define a method that an implementing subclass is expected to provide a concrete implementation for. Any attempt to invoke an ABSTRACT method directly will raise a SYNTAX condition.

If the EXTERNAL option is specified, then spec identifies a method in an external native library that will be invoked as the named method. The spec is a literal string containing a series of whitespace delimited tokens defining the external method. The first token must be the word LIBRARY, which indicates the method resides in a native library of the type allowed on a ::REQUIRES directive. The second token must identify the name of the external library. The external library is located using platform-specific mechanisms for loading libraries. For Unix-based systems, the library name is case-sensitive. The third token is optional and specifies the name of the method within the library package. If not specified, the ::METHOD name is used. The target package method name is case insensitive.

Example:

-- creates method INIT from method RegExp_Init
-- in library rxregexp
::METHOD INIT EXTERNAL "LIBRARY rxregexp RegExp_Init"

-- creates method INIT from method POS
-- in library rxregexp
::METHOD POS EXTERNAL "LIBRARY rxregexp"

If the ATTRIBUTE option is specified with the EXTERNAL option, then two method objects need to be created. The target method name is appended to the string "GET" to derive the name of the getter attribute method. To generate the setter attribute method, the name is appended to the string "SET".

Example:

-- maps "NAME" method to "GETNAME" and
-- "NAME=" to "SETNAME"
::METHOD name ATTRIBUTE EXTERNAL "LIBRARY mylib"

-- maps "ADDRESS" method to "GETMyAddress" and
-- "ADDRESS=" to "SETMyAddress"
::METHOD address ATTRIBUTE EXTERNAL "LIBRARY mylib MyAddress"

Notes:

1. You can specify all options in any order.

2. If you specify the PRIVATE option, the created methods are private methods. Private methods have restricted access rules on how they can be invoked. See Public versus Private Methods for details of how private methods can be used. If you omit the PRIVATE option or specify PUBLIC, the method is a public method that any sender can activate.

3. If you specify the UNGUARDED option, the method can be called while other methods are active on the same object. If you do not specify UNGUARDED, the method requires exclusive use of the
object variable pool; it can run only if no other method that requires exclusive use of the object variable pool is active on the same object.

4. If you specify the PROTECTED option, the method is a protected method. (See The Security Manager for more information.) If you omit the PROTECTED option or specify UNPROTECTED, the method is not protected.

5. If you specify ATTRIBUTE, ABSTRACT, or EXTERNAL, another directive (or the end of the program) must follow the ::METHOD directive.

6. It is an error to specify ::METHOD more than once within the same class and use the same methodname.

3.5. ::OPTIONS

The ::OPTIONS directive defines default values for numeric and trace settings for all Rexx code contained within a package.

```
>---::OPTIONS-----------------------------+-------------------+-------------->
 +DIGITS-digits++  +FORM-form+  +FUZZ-fuzz+
>------------------------------------------------------------------>
 +TRACE-trace++
```

Any of the options may be specified on a single ::OPTIONS directive in any order. If an option is specified more than once, the last specified value will the be one used. If more than one ::OPTIONS directive appears in a source file, the options are processed in the order they appear and the effect is accumulative. If a given option type is specified on more than directive, the last specified will be the value used.

The specified options will override the normal default settings for all Rexx code contained in the source file. For example,

```
::OPTIONS DIGITS 20
```

would direct that all method and routine code defined in this source package execute with an initial NUMERIC DIGITS setting of 20 digits. The ::OPTIONS directive controls only the initial setting. A method or routine may change the current setting with the NUMERIC DIGITS instruction as normal. The values specified with ::OPTIONS only apply to code that appears in the same source file. It does not apply to code in other source files that may reference or use this code. For example, a subclass of a class defined in this source package will not inherit the ::OPTIONS settings if the subclass code is located in a different source package.

The following options may be specified on an ::OPTIONS directive:
DIGITS controls the precision to which arithmetic operations and built-in functions are evaluated. The value digits must be a symbol or string that is a valid positive whole number value and must be larger than the current FUZZ ::OPTIONS setting. The package value can be retrieved using the Package class digits method. There is no limit to the value for DIGITS (except the amount of storage available), but high precisions are likely to require a great amount of processing time. It is recommended that you use the default value whenever possible.

FORM controls the form of exponential notation for the result of arithmetic operations and built-in functions. This can be either SCIENTIFIC (in which case only one, nonzero digit appears before the decimal point) or ENGINEERING (in which case the power of 10 is always a multiple of 3). The default is SCIENTIFIC. The subkeywords SCIENTIFIC or ENGINEERING must be specified as symbols. The package value can be retrieved using the Package class form method.

FUZZ controls how many digits, at full precision, are ignored during a numeric comparison operation. (See Numeric Comparisons.) The value fuzz must be a symbol or string that is a valid positive whole number value and must be smaller than the current DIGIT ::OPTIONS setting. The package value can be retrieved using the Package class fuzz method. NUMERIC FUZZ temporarily reduces the value of NUMERIC DIGITS by the NUMERIC FUZZ value during every numeric comparison. The numbers are subtracted under a precision of DIGITS minus FUZZ digits during the comparison and are then compared with 0.

TRACE controls the tracing action (that is, how much is displayed to the user) during the processing of all Rexx code contained in the package. Tracing describes some or all of the clauses in a program, producing descriptions of clauses as they are processed. TRACE is mainly used for debugging. The value trace must be one of the Trace Alphabetic Character (Word) Options valid for the Trace instruction. The package value can be retrieved using the Package class trace method.

### 3.6. ::REQUIRES

The ::REQUIRES directive specifies that the program requires access to the classes and objects of the Rexx program programname.

```plaintext
>>> :REQUIRES---"programname"---+--------+----------------------<
    +LIBRARY++
```

If the LIBRARY option is not specified, all public classes and routines defined in the named program are made available to the executing program. The programname is a literal string or a symbol that is taken as a constant. The string or symbol programname can be any string or symbol that is valid as the target of a CALL instruction. The program programname is called as an external routine with no arguments. The program is searched for using normal external program search order. See Search Order for details. The main program code, which precedes the first directive instruction, is run.
Chapter 3. Directives

If any Rexx code preceeds the first directive in *programname* then that code is executed at the time the ::REQUIRES is processed by the interpreter. This will be executed prior to executing the main Rexx program in the file that specifies the ::REQUIRES statement.

If the LIBRARY option is specified, *programname* is the name of an external native library that is required by this program. The library will be loaded using platform-specific mechanisms, which generally means the library name is case sensitive. Any routines defined in the library will be made available to all programs running in the process. If the native library cannot be loaded, the program will not be permitted to run. All LIBRARY ::REQUIRES directives will be processed before ::REQUIRES for Rexx programs, which will ensure that the native libraries are available to the initialization code of the Rexx packages.

::REQUIRES directives can be placed anywhere after the main section of code in the package. The order of ::REQUIRES directives determines the search order for classes and routines defined in the named programs and also the load order of the referenced files. Once a program is loaded by a ::REQUIRES statement in a program, other references to that same program by ::REQUIRES statements in other programs will resolve to the previously loaded program. The initialization code for the ::REQUIRES file will only be executed on the first reference.

The following example illustrates that two programs, ProgramA and ProgramB, can both access classes and routines that another program, ProgramC, contains. (The code at the beginning of ProgramC runs prior to the start of the main Rexx program.)

The language processor uses local routine definitions within a program in preference to routines of the same name accessed through ::REQUIRES directives. Local class definitions within a program override classes of the same name in other programs accessed through ::REQUIRES directives.

Another directive, or the end of the program, must follow a ::REQUIRES directive. Only null clauses can appear between them.
3.7. ::ROUTINE

The ::ROUTINE directive creates named routines within a program.

```
++PRIVATE++
>>-::ROUTINE--routinename--+-PUBLIC--+-EXTERNAL-spec-->
```

The `routinename` is a literal string or a symbol that is taken as a constant. Only one ::ROUTINE directive can appear for any `routinename` in a program.

If the EXTERNAL option is not specified, the ::ROUTINE directive starts a routine, which is ended by another directive or the end of the program.

If you specify the PUBLIC option, the routine is visible beyond its containing Rexx program to any other program that references this program with a ::REQUIRES directive. If you do not specify the PUBLIC option, the routine is visible only within its containing Rexx program.

Routines you define with the ::ROUTINE directive behave like external routines. In the search order for routines, they follow internal routines and built-in functions but precede all other external routines.

**Example:**

```rexx
::class c
::method a
call r "A" /* displays "In method A" */

::method b
call r "B" /* displays "In method B" */

::routine r
use arg name
say "In method" name
```

If the EXTERNAL option is specified, then `spec` identifies a routine in an external native library that will be defined as the named routine for this program. The `spec` is a literal string containing a series of whitespace delimited tokens defining the external function. The first token identifies the type of native routine to locate:

**LIBRARY**

Identifies a routine in an external native library of the type supported by the ::REQUIRES directive. The second token must identify the name of the external library. The external library is located using platform-specific mechanisms for loading libraries. For Unix-based systems, the library name is case-sensitive. The third token is optional and specifies the name of the routine within the library package. If not specified, the ::ROUTINE name is used. The routine name is not case sensitive.

**REGISTERED**

Identifies a routine in an older-style Rexx function package. The second token must identify the name of the external library. The external library is located using platform-specific mechanisms for loading libraries. For Unix-based systems, the library name is case-sensitive. The third token is optional and specifies the name of the function within the library package. If not specified, the ::ROUTINE name is used. Loading of the function will be attempted using the name as given and as
all uppercase. Using REGISTERED is the equivalent of loading an external function using the RXFUNCADD() built-in function. See .METHODS for more details.

Example:

-- load a function from rxmath library
::routine RxCalcPi EXTERNAL "LIBRARY rxmath"
-- same function, but a different internal name
::routine Pi EXTERNAL "LIBRARY rxmath RxCalcPi"
-- same as call rxfuncadd "SQLLoadFuncs", "rexxsql", "SQLLoadFuncs"
::routine SQLLoadFuncs "REGISTERED rexxsql SQLLoadFuncs"

Notes:

1. It is an error to specify ::ROUTINE with the same routine name more than once in the same program. It is not an error to have a local ::ROUTINE with the same name as another ::ROUTINE in another program that the ::REQUIRES directive accesses. The language processor uses the local ::ROUTINE definition in this case.

2. Calling an external Rexx program as a function is similar to calling an internal routine. For an external routine, however, the caller’s variables are hidden and the internal values (NUMERIC settings, for example) start with their defaults.

Note: If you specify the same ::ROUTINE routinename more than once in different programs, the last one is used. Using more than one ::ROUTINE routinename in the same program produces an error.
Chapter 4. Objects and Classes

This chapter provides an overview of the Rexx class structure.

A Rexx object consists of object methods and object variables ("attributes"). Sending a message to an object causes the object to perform some action; a method whose name matches the message name defines the action that is performed. Only an object’s methods can access the object variables belonging to an object. EXPOSE instructions within an object’s methods specify which object variables the methods will use. Any variables not exposed are local to the method and are dropped on return from a method.

You can create an object by sending a message to a class object—typically a "new" method. An object created from a class is an instance of that class. The methods a class defines for its instances are called the instance methods of that class. These are the object methods that are available for every instance of the class. Classes can also define class methods, which are a class’s own object methods.

Note: When referring to instance methods (for objects other than classes) or class methods (for classes), this book uses the term methods when the meaning is clear from the context. When referring to instance methods and class methods of classes, this book uses the qualified terms to avoid possible confusion.

4.1. Types of Classes

There are four kinds of classes:

- Object classes
- Mixin classes
- Abstract classes
- Metaclasses

The following sections explain these.

4.1.1. Object Classes

An object class is a factory for producing objects. An object class creates objects (instances) and provides methods that these objects can use. An object acquires the instance methods of the class to which it belongs at the time of its creation. If a class gains additional methods, objects created before the definition of these methods do not acquire the new or changed methods.

The instance variables within an object are created on demand whenever a method EXPOSEs an object variable. The class creates the object instance, defines the methods the object has, and the object instance completes the job of constructing the object.

The String class and the Array Class are examples of object classes.
4.1.2. Mixin Classes

Classes can inherit from more than the single superclass from which they were created. This is called *multiple inheritance*. Classes designed to add a set of instance and class methods to other classes are called *Mixin classes*, or simply mixins.

You can add mixin methods to an existing class by sending an INHERIT message or using the INHERIT option on the ::CLASS directive. In either case, the class to be inherited must be a mixin. During both class creation and multiple inheritance, subclasses inherit both class and instance methods from their superclasses.

Mixins are always associated with a *Base class*, which is the mixin’s first non-mixin superclass. Any subclass of the mixin’s base class can (directly or indirectly) inherit a mixin; other classes cannot. For example, a mixin class created as a subclass of the Array class can only be inherited by other Array subclasses. Mixins that use the Object class as a base class can be inherited by any class.

To create a new mixin class, you send a MIXINCLASS message to an existing class or use the ::CLASS directive with the MIXINCLASS option. A mixin class is also an object class and can create instances of the class.

4.1.3. Abstract Classes

*Abstract classes* provide definitions for instance methods and class methods but are not intended to create instances. Abstract classes often define the message interfaces that subclasses should implement.

You create an abstract class like object or mixin classes. No extra messages or keywords on the ::CLASS directive are necessary. Rexx does not prevent users from creating instances of abstract classes. It is possible to create abstract methods on a class. An abstract method is a placeholder that subclasses are expected to override. Failing to provide a real method implementation will result in an error when the abstract version is called.

4.1.4. Metaclasses

A *metaclass* is a class you can use to create another class. The only metaclass that Rexx provides is .Class, the Class class. The Class class is the metaclass of all the classes Rexx provides. This means that instances of .Class are themselves classes. The Class class is like a factory for producing the factories that produce objects.

To change the behavior of an object that is an instance, you generally use subclassing. For example, you can create Statarray, a subclass of the Array class. The statArray class can include a method for computing a total of all the numeric elements of an array.

```rexx
/* Creating an array subclass for statistics */
::class statArray subclass array public

::method init /* Initialize running total and forward to superclass */
expose total
  total = 0
  /* init describes the init method. */
```
forward class (super)

::method put /* Modify to increment running total */
  expose total
  use arg value
  total = total + value /* Should verify that value is numeric!!! */
  forward class (super)

::method "[]=" /* Modify to increment running total */
  forward message "PUT"

::method remove /* Modify to decrement running total */
  expose total
  use arg index
  forward message "AT" continue
  total = total - result
  forward class (super)

::method average /* Return the average of the array elements */
  expose total
  return total / self~items

::method total /* Return the running total of the array elements */
  expose total
  return total

You can use this method on the individual array instances, so it is an instance method.

However, if you want to change the behavior of the factory producing the arrays, you need a new class method. One way to do this is to use the ::METHOD directive with the CLASS option. Another way to add a class method is to create a new metaclass that changes the behavior of the Statarray class. A new metaclass is a subclass of .class.

You can use a metaclass by specifying it in a SUBCLASS or MIXINCLASS message or on a ::CLASS directive with the METACLASS option.

If you are adding a highly specialized class method useful only for a particular class, use the ::METHOD directive with the CLASS option. However, if you are adding a class method that would be useful for many classes, such as an instance counter that counts how many instances a class creates, you use a metaclass.

The following examples add a class method that keeps a running total of instances created. The first version uses the ::METHOD directive with the CLASS option. The second version uses a metaclass.

Version 1

/* Adding a class method using ::METHOD */

a = .point~new(1,1) /* Create some point instances */
say "Created point instance" a
b = .point~new(2,2) /* create another point instance */
say "Created point instance" b
c = .point~new(3,3) /* create another point instance */
say "Created point instance" c /* ask the point class how many */
Chapter 4. Objects and Classes

/* instances it has created */
say "The point class has created" .point~instances "instances."

::class point public /* create Point class */
expose instanceCount /* Initialize instanceCount */
instanceCount = 0 /* Initialize instanceCount */
forward class (super) /* Forward INIT to superclass */

::method new
expose instanceCount /* Creating a new instance */
instanceCount = instanceCount + 1 /* Bump the count */
forward class (super) /* Forward NEW to superclass */

::method instances
expose instanceCount /* Return the instance count */
return instanceCount

::method init
expose xVal yVal /* Set object variables */
use arg xVal, yVal /* as passed on NEW */

::method string
expose xVal yVal /* Use object variables */
return "("xVal","yVal")" /* to return string value */

Version 2

/* Adding a class method using a metaclass */

a = .point~new(1,1) /* Create some point instances */
say "Created point instance" a
b = .point~new(2,2)
say "Created point instance" b
c = .point~new(3,3)
say "Created point instance" c

/* ask the point class how many */
/* instances it has created */
say "The point class has created" .point~instances "instances."

::class InstanceCounter subclass class /* Create a new metaclass that */
/* will count its instances */

::method init
expose instanceCount /* Initialize instanceCount */
instanceCount = 0 /* Initialize instanceCount */
forward class (super) /* Forward INIT to superclass */

::method new
expose instanceCount /* Creating a new instance */
4.2. Creating and Using Classes and Methods

You can define a class using either directives or messages.

To define a class using directives, you place a ::CLASS directive after the main part of your source program:

```::class "Account"
```

This creates an Account class that is a subclass of the Object class. Object is the default superclass if one is not specified. (See The Object Class for a description of the Object class.) The string "Account" is a string identifier for the new class. The string identifier is both the internal class name and the name of the environment symbol used to locate your new class instance.

Now you can use ::METHOD directives to add methods to your new class. The ::METHOD directives must immediately follow the ::CLASS directive that creates the class.

```::method type
 return "an account"
```

```::method "name=
 expose name
 use arg name
```

```::method name
 expose name
 return name
```

This adds the methods TYPE, NAME, and NAME= to the Account class.

You can create a subclass of the Account class and define a method for it:

```::class "Savings" subclass account
```
Chapter 4. Objects and Classes

::method type
    return "a savings account"

Now you can create an instance of the Savings class with the NEW method (see NEW) and send TYPE, NAME, and NAME= messages to that instance:

asav = .savings~new
say asav~type
asav"name = "John Smith"

The Account class methods NAME and NAME= create a pair of access methods to the account object variable NAME. The following directive sequence creates the NAME and NAME= methods:

::method "name="
    expose name
    use arg name
::method name
    expose name
    return name

You can replace this with a single ::ATTRIBUTE directive. For example, the directive

::attribute name

adds two methods, NAME and NAME= to a class. These methods perform the same function as the NAME and NAME= methods in the original example. The NAME method returns the current value of the object variable NAME; the NAME= method assigns a new value to the object variable NAME.

In addition to defining operational methods and attribute methods, you can add "constant" methods to a class using the ::CONSTANT directive. The ::CONSTANT directive will create both a class method and an instance method to the class definition. The constant method will always return the same constant value, and can be invoked by sending a message to either the class or an instance method. For example, you might add the following constant to your Account class:

::constant checkingMinimum 200

This value can be retrieved using either of the following methods

say .Account~checkingMinimum -- displays "200"
asave = .savings~new
say asave~checkingMinimum -- also displays "200"

4.2.1. Using Classes

When you create a new class, it is always a subclass of an existing class. You can create new classes with the ::CLASS directive or by sending the SUBCLASS or MIXINCLASS message to an existing class. If you specify neither the SUBCLASS nor the MIXINCLASS option on the ::CLASS directive, the superclass for the new class is the Object class, and it is not a mixin class.

Example of creating a new class using a message:

persistence = .object~mixinclass("Persistence")
myarray=.array~subclass("myarray")~`inherit(persistence)

Example of creating a new class using the directive:

::class persistence mixinclass object
::class myarray subclass array inherit persistence

### 4.2.2. Scope

A *scope* refers to the methods and object variables defined for a single class (not including the superclasses). Only methods defined in a particular scope can access the object variables within that scope. This means that object variables in a subclass can have the same names as object variables used by a superclass, because the variables are created at different scopes.

### 4.2.3. Defining Instance Methods with SETMETHOD or ENHANCED

In Rexx, methods are usually associated with instances using classes, but it is also possible to add methods directly to an instance using the SETMETHOD (see SETMETHOD) or ENHANCED (see ENHANCED) method.

All subclasses of the Object class inherit SETMETHOD. You can use SETMETHOD to create one-off objects, objects that must be absolutely unique so that a class that is capable of creating other instances is not necessary. The Class class also provides an ENHANCED method that lets you create new instances of a class with additional methods. The methods and the object variables defined on an object with SETMETHOD or ENHANCED form a separate scope, like the scopes the class hierarchy defines.

### 4.2.4. Method Names

A method name can be any string. When an object receives a message, the language processor searches for a method whose name matches the message name in uppercase.

**Note:** The language processor also translates the specified name of all methods added to objects into uppercase characters.

You must surround a method name with quotation marks when it contains characters that are not allowed in a symbol (for example, the operator characters). The following example creates a new class (the Cost class), defines a new method (%), creates an instance of the Cost class (mycost), and sends a % message to mycost:

```rexx
cost=.object~subclass("A cost")
cost~define("%", 'expose p; say "Enter a price."; pull p; say p*1.07;')
mycost=cost~new
mycost~~%  /* Produces: Enter a price. */
/* If the user specifies a price of 100, */
4.2.5. Default Search Order for Method Selection

The search order for a method name matching the message is for:

1. A method the object itself defines with SETMETHOD or ENHANCED. (See SETMETHOD.)
2. A method the object’s class defines. (Note that an object acquires the instance methods of the class to which it belongs at the time of its creation. If a class gains additional methods, objects created before the definition of these methods do not acquire these methods.)
3. A method that a superclass of the object’s class defines. This is also limited to methods that were available when the object was created. The order of the INHERIT (see INHERIT) messages sent to an object’s class determines the search order of the superclass method definitions.

This search order places methods of a class before methods of its superclasses so that a class can supplement or override inherited methods.

If the language processor does not find a match for the message name, the language processor checks the object for a method name UNKNOWN. If it exists, the language processor calls the UNKNOWN method and returns as the message result any result the UNKNOWN method returns. The UNKNOWN method arguments are the original message name and a Rexx array containing the original message arguments.

If the object does not have an UNKNOWN method, the language processor raises a NOMETHOD condition. If there are no active traps for the NOMETHOD condition, a syntax error is raised.

4.2.6. Defining an UNKNOWN Method

When an object that receives a message does not have a matching message name, the language processor checks if the object has a method named UNKNOWN. If the object has an UNKNOWN method, the language processor calls UNKNOWN, passing two arguments. The first argument is the name of the method that was not located. The second argument is an array containing the arguments passed with the original message.

For example, the following UNKNOWN method will print out the name of the invoked method and then invoke the same method on another object. This can be used track the messages that are sent to an object:

```
::method unknown
expose target -- will receive all of the messages
use arg name, arguments
say name "invoked with" arguments~toString
forward to(target) -- send along the message with the original args
```

4.2.7. Changing the Search Order for Methods

You can change the usual search order for methods by:
1. Ensuring that the receiver object is the sender object. (You usually do this by specifying the special variable \texttt{SELF}.

2. Specifying a colon and a class symbol after the message name. The class symbol can be a variable name or an environment symbol. It identifies the class object to be used as the starting point for the method search.

The class object must be a superclass of the class defining the active method, or, if you used \texttt{SETMETHOD} to define the active method, the object's own class. The class symbol is usually the special variable \texttt{SUPER} (see \texttt{SUPER}) but it can be any environment symbol or variable name whose value is a valid class.

Suppose you create an Account class that is a subclass of the Object class, define a \texttt{TYPE} method for the Account class, and create the Savings class that is a subclass of Account. You could define a \texttt{TYPE} method for the Savings class as follows:

\begin{verbatim}
  savings~define("TYPE", 'return "a savings account"')
\end{verbatim}

You could change the search order by using the following line:

\begin{verbatim}
  savings~define("TYPE", 'return self~type:super "(savings)"')
\end{verbatim}

This changes the search order so that the language processor searches for the \texttt{TYPE} method first in the Account superclass (rather than in the Savings subclass). When you create an instance of the Savings class (\texttt{asav}) and send a \texttt{TYPE} message to \texttt{asav}:

\begin{verbatim}
  say asav~type
\end{verbatim}

an account (savings) is displayed. The \texttt{TYPE} method of the Savings class calls the \texttt{TYPE} method of the Account class, and adds the string \texttt{(savings)} to the results.

### 4.2.8. Public and Private Methods

A method can be public or private. Any object can send a message that runs a public method. A private method can only be invoked from specific calling contexts. These contexts are:

1. From within a method owned by the same class as the target. This is frequently the same object, accessed via the special variable \texttt{SELF}. Private methods of an object can also be accessed from other instances of the same class (or subclass instances).

2. From within a method defined at the same class scope as the method. For example:

\begin{verbatim}
::class Savings
::method newCheckingAccount CLASS
  instance = self~new
  instance~makeChecking
  return instance

::method makeChecking private
  expose checking
  checking = true
\end{verbatim}
Chapter 4. Objects and Classes

The newCheckingAccount CLASS method is able to invoke the makeChecking method because the scope of the makeChecking method is .Savings.

3. From within an instance (or subclass instance) of a class to a private class method of its class. For example:

::class Savings
::method init class
  expose counter
  counter = 0

::method allocateAccountNumber private class
  expose counter
  counter = counter + 1
  return counter

::method init
  expose accountNumber
  accountNumber = self~class~allocateAccountNumber

The instance init method of the Savings class is able to invoke the allocateAccountNumber private method of the .Savings class object because it is owned by an instance of the .Savings class.

Private methods include methods at different scopes within the same object. This allows superclasses to make methods available to their subclasses while hiding those methods from other objects. A private method is like an internal subroutine. It shields the internal information of an object to outsiders, but allowing objects to share information with each other and their defining classes.

4.2.9. Initialization

Any object requiring initialization at creation time must define an INIT method. If this method is defined, the class object runs the INIT method after the object is created. If an object has more than one INIT method (for example, it is defined in several classes), each INIT method must forward the INIT message up the hierarchy to complete the object’s initialization.

Example:

asav = .savings~new(1000.00, 6.25)
say asav~type
asav~name = "John Smith"

::class Account

::method INIT
  expose balance
  use arg balance

::method TYPE
  return "an account"

::method name attribute

::class Savings subclass Account
Chapter 4. Objects and Classes

::method INIT
  expose interest_rate
  use arg balance, interest_rate
  self~init:super(balance)

::method type
  return "a savings account"

The NEW method of the Savings class object creates a new Savings object and calls the INIT method of the new object. The INIT method arguments are the arguments specified on the NEW method. In the Savings INIT method, the line:

self~init:super(balance)

calls the INIT method of the Account class, using just the balance argument specified on the NEW message.

4.2.10. Object Destruction and Uninitialization

Object destruction is implicit. When an object is no longer in use, Rexx automatically reclaims its storage. If the object has allocated other system resources, you must release them at this time. (Rexx cannot release these resources, because it is unaware that the object has allocated them.)

Similarly, other uninitialization processing may be needed, for example, by a message object holding an unreported error. An object requiring uninitialization should define an UNINIT method. If this method is defined, Rexx runs it before reclaiming the object’s storage. If an object has more than one UNINIT method (defined in several classes), each UNINIT method is responsible for sending the UNINIT method up the object hierarchy.

4.2.11. Required String Values

Rexx requires a string value in a number of contexts within instructions and built-in function calls.

- DO statements containing expr or exprf
- Substituted values in compound variable names
- Commands to external environments
- Commands and environment names on ADDRESS instructions
- Strings for ARG, PARSE, and PULL instructions to be parsed
- Parenthesized targets on CALL instructions
- Subsidiary variable lists on DROP, EXPOSE, and PROCEDURE instructions
- Instruction strings on INTERPRET instructions
- DIGITS, FORM, and FUZZ values on NUMERIC instructions
- Options strings on OPTIONS instructions
Chapter 4. Objects and Classes

- Data queue strings on PUSH and QUEUE instructions
- Label names on SIGNAL VALUE instructions
- Trace settings on TRACE VALUE instructions
- Arguments to built-in functions
- Variable references in parsing templates
- Data for PUSH and QUEUE instructions to be processed
- Data for the SAY instruction to be displayed
- Rexx dyadic operators when the receiving object (the object to the left of the operator) is a string

If you supply an object other than a string in these contexts, by default the language processor converts it to some string representation and uses this. However, the programmer can cause the language processor to raise the NOSTRING condition when the supplied object does not have an equivalent string value.

To obtain a string value, the language processor sends a REQUEST("STRING") message to the object. Strings and other objects that have string values return the appropriate string value for Rexx to use. (This happens automatically for strings and for subclasses of the String class because they inherit a suitable MAKESTRING method from the String class.) For this mechanism to work correctly, you must provide a MAKESTRING method for any other objects with string values.

For other objects without string values (that is, without a MAKESTRING method), the action taken depends on the setting of the NOSTRING condition trap. If the NOSTRING condition is being trapped (see Conditions and Condition Traps), the language processor raises the NOSTRING condition. If the NOSTRING condition is not being trapped, the language processor sends a STRING message to the object to obtain its readable string representation (see the STRING method of the Object class STRING) and uses this string.

When comparing a string object with the Nil object, if the NOSTRING condition is being trapped, then

```plaintext
if string = .nil
```

will raise the NOSTRING condition, whereas

```plaintext
if .nil = string
```

will not as the Nil object’s "=" method does not expect a string as an argument.

**Example:**

```plaintext
d = .directory~new
say substr(d,5,7) /* Produces "rectory" from "a Directory" */
signal on nostring
say substr(d,5,7) /* Raises the NOSTRING condition */
say substr(d~string,3,6) /* Displays "Direct" */
```

For arguments to Rexx object methods, different rules apply. When a method expects a string as an argument, the argument object is sent the REQUEST("STRING") message. If REQUEST returns the Nil object, then the method raises an error.
4.2.12. Concurrency
Rexx supports concurrency, multiple methods running simultaneously on a single object. See Concurrency for a full description of concurrency.

4.3. Overview of Classes Provided by Rexx
This section gives a brief overview of the classes and methods Rexx defines.

4.3.1. The Class Hierarchy
Rexx provides the following classes belonging to the object class:

- Alarm class
- Array class
- Class class
- Collection class
  - MapCollection class
  - OrderedCollection class
  - SetCollection class
- Comparable class
- Orderable class
- Comparator class
  - CaselessColumnComparator class
  - CaselessComparator class
  - CaselessDescendingComparator class
  - ColumnComparator class
  - DescendingComparator class
  - InvertingComparator class
- DateTime class
- Directory class
  - Properties class
- InputOutputStream class
Chapter 4. Objects and Classes

- Stream class
- InputStream class
- List class
- Message class
- Method class
- Method class
- Routine class
- MutableBuffer class
- OutputStream class
- Queue class
  - CircularQueue class
- RegularExpression class
- Relation class
  - Bag class
- RexxQueue class
- Stem class
- String class
- Supplier class
  - StreamSupplier class
- Table class
  - Set class
- IdentityTable class
- TimeSpan class
- WeakReference class
- RexxContext class
- Buffer class
- Pointer class

(The classes are in a class hierarchy with subclasses indented below their superclasses.)

Note that there might also be other classes in the system, depending on the operating system. Additional classes may be accessed by using an appropriate ::requires directive to load the class definitions.
The following figures show Rexx built-in classes.

**Figure 4-1. Classes and Inheritance (part 1 of 9)**

```
Object
  ├─ Alarm
  │   ├─ Collection
  │     ├─ MapCollection
  │     └─ OrderedCollection
  │         └─ SetCollection
  └─ Array
```

**Figure 4-2. Classes and Inheritance (part 2 of 9)**

```
Object
  └─ Comparator
     ├─ CaselessColumnComparator
     ├─ CaselessComparator
     └─ ColumnComparator
     └─ CaselessDescendingComparator
         └─ DescendingComparator
             └─ InvertingComparator
  └─ DateTime
```
4.3.2. Class Library Notes

The chapters that follow describe the classes and other objects that Rexx provides and their available methods. Rexx provides the objects listed in these sections and they are generally available to all methods through environment symbols (see Environment Symbols).

Notes:

1. In the method descriptions in the chapters that follow, methods that return a result begin with the word "returns".
2. For [] and []= methods, the syntax diagrams include the index or indexes within the brackets. These diagrams are intended to show how you can use these methods. For example, to retrieve the first element of a one-dimensional array named Array1, you would typically use the syntax:
   
   ```
   Array1[1]
   ```
   
   rather than:
   
   ```
   Array1"[]=1"(1)
   ```
even though the latter is valid and equivalent. For more information, see Message Terms and Message Instructions.

3. When the argument of a method must be a specific kind of object (such as array, class, method, or string) the variable you specify must be of the same class as the required object or be able to produce an object of the required kind in response to a conversion message. In particular, subclasses are acceptable in place of superclasses (unless overridden in a way that changes superclass behavior), because they inherit a suitable conversion method from their Rexx superclass.

The isA method of the Object class can perform this validation.
Chapter 5. The Built-in Classes

This chapter describes all of the Rexx built-in classes.

Fundamental Classes
This set of classes are the fundamental building blocks for all other classes. It includes the Object class, the Class class, the String class, the Method class, and the Routine class, and the Package class, and the Message class.

Stream Classes
This set of classes implement the classic Rexx streams. It includes the Stream class, the InputStream class, the OutputStream class, and the InputOutputStream class.

Collection Classes
This set of classes implement object collections. It includes the Directory class, the Properties class, the Relation class, the Stem class, the Table class, the IdentityTable class, the Array class, the List class, the Queue class, the CircularQueue class, the Bag class, and the Set class.

Utility Classes
This set of classes are utility in nature and hard to classify. It includes the Alarm class, the Comparable class, the Comparator class, the Orderable class, the DateTime class, the MutableBuffer class, the RegularExpression class, the RexxContext class, the RexxQueue class, the StreamSupplier class, the Supplier class, the TimeSpan class and the WeakReference class.

5.1. The Fundamental Classes

This section describes the Rexx fundamental classes.

5.1.1. The Object Class
The Object class is the root of the class hierarchy. The instance methods of the Object class are, therefore, available on all objects.
Figure 5-1. The Object class and methods

```
Object

new

|= == |== <> >=
class
copy
defaultName
hasMethod
identityHash
init
instanceMethod
instanceMethods
isA
instanceOf
objectName
objectName=
request
run
send
sendWith
setMethod
start
startWith
string
unsetMethod
```

**Note:** The Object class also has available class methods that its metaclass, the Class class, defines.

### 5.1.1.1. new (Class Method)

```
>>>new----------------------------->
```

Returns a new instance of the receiver class.
5.1.1.2. Operator Methods

>>>-comparison_operator(argument)---------------------------->

Returns 1 (true) or 0 (false), the result of performing a specified comparison operation.
For the Object class, if argument is the same object as the receiver object, the result is 1 (true), otherwise 0 (false) is returned. Subclasses may override this method to define equality using different criteria. For example, the String class determines equality based on the value of the string data.

Note: The MapCollection classes such as Table and Relation use the == operator combined with the hashCode method to determine index and item equivalence. It is generally necessary for a class to override both the hashCode method and the == operator method to maintain the contract specified for the hashCode method. See hashCode Method for details on the contract.

The comparison operators you can use in a message are:

=, ==
  True if the terms are the same object.

\=, < >, <+>, \==
  True if the terms are not the same object (inverse of =).

5.1.1.3. Concatenation Methods

>>>-concatenation_operator(argument)---------------------------->

Returns a new string that is the concatenation the of receiver object’s string value with argument. (See String Concatenation.) The concatenation_operator can be:

"
  concatenates without an intervening blank. The abuttal operator "" is the null string. The language processor uses the abuttal operator to concatenate two terms that another operator does not separate.

|
  concatenates without an intervening blank.

" 
  concatenates with one blank between the receiver object and the argument. (The operator " " is a blank.)

5.1.1.4. class

>>>-class----------------------------------------------->

5.1.1.5. copy

Returns a copy of the receiver object. The copied object has the same methods as the receiver object and an equivalent set of object variables, with the same values.

Example:

myarray=.array~of("N","S","E","W")
/* Copies array myarray to array directions */
directions=myarray~copy

Note: The copy method is a “shallow copy”. Only the target object is copied. Additional objects referenced by the target object are not copied. For example, copying an Array object instance only copies the array, it does not copy any of the objects stored in the array.

5.1.1.6. defaultName

Returns a short human-readable string representation of the object. The exact form of this representation depends on the object and might not alone be sufficient to reconstruct the object. All objects must be able to produce a short string representation of themselves in this way, even if the object does not have a string value. See Required String Values for more information. The defaultName method of the Object class returns a string that identifies the class of the object, for example, an Array or a Directory. See also objectName and string. See objectName= for an example using defaultName.

5.1.1.7. hashCode

Returns a string value that is used as a hash value for MapCollections such as Table, Relation, Set, Bag, and Directory. MapCollections use this string value to hash an object for hash table-based searches.

Object implementations are expected to abide by a general contract for hash code usage:

• Whenever hashCode is invoked on the same object more than once, hashCode must return the same hashcode value, provided than none of the internal information the object uses for an "==" comparison has changed.

• If two object instances compare equal using the "==" operator, the hashCode methods for both object instances must return the same value.
• It is not required that two object instances that compare unequal using "==" return different hash code values.

• Returning a wide range of hash values will produce better performance when an object is used as an index for a MapCollection. A return value of 4 string characters is recommended. The characters in the hash value may be any characters from ’00’x to ’ff’x, inclusive.

5.1.1.8. hasMethod

>>-hasMethod(methodname)---------------------------------------><

Returns 1 (true) if the receiver object has a method named methodname (translated to uppercase). Otherwise, it returns 0 (false).

Note: The hasMethod object will return true even if the target method is defined as private. A private method has restricted access rules, so it’s possible to receive an unknown method error (error 97) when invoking methodname even if hasMethod indicates the method exists. See Public versus Private Methods for private method restrictions.

5.1.1.9. identityHash

>>-identityHash------------------------------------------------><

Returns a unique identity number for the object. This number is guaranteed to be unique for the receiver object until the object is garbage collected.

5.1.1.10. init

>>-init--------------------------------------------------------><

Performs any required object initialization. Subclasses of the Object class can override this method to provide more specific initialization.

5.1.1.11. instanceMethod

>>-instanceMethod(methodname)----------------------------------><

Returns the corresponding Method class instance if the methodname is a valid method of the class. Otherwise it returns the Nil object.

5.1.1.12. instanceMethods

>>-instanceMethods(class)----------------------------------><
Chapter 5. The Builtin Classes

Returns a Supplier instance containing the names and corresponding method objects defined by \texttt{class}. If the receiver object is not an instance of \texttt{class}, the Nil object is returned.

5.1.1.13. \texttt{isA}

\texttt{>>-isA(class)}

\textbf{Note}: This method is an alias of the \texttt{isInstanceOf} method.

5.1.1.14. \texttt{isInstanceOf}

\texttt{>>-isInstanceOf(class)}

Returns \texttt{.true} ("1") if the object is an instance of the specified \texttt{class}, otherwise it returns \texttt{.false} ("0"). An object is an instance of a class if the object is directly an instance of the specified \texttt{class} or if \texttt{class} is in the object’s direct or mixin class inheritance chain. For example:

\begin{verbatim}
"abc``isInstanceOf(.string) -> 1
"abc``isInstanceOf(.object) -> 1
"abc``isInstanceOf(.mutablebuffer) -> 0
\end{verbatim}

5.1.1.15. \texttt{objectName}

\texttt{>>-objectName}

Returns any name set on the receiver object using the \texttt{objectName=} method. If the receiver object does not have a name, this method returns the result of the \texttt{defaultName} method. See Required String Values for more information. See the \texttt{objectName=} method for an example using \texttt{objectName}.

5.1.1.16. \texttt{objectName=}

\texttt{>>-objectName=(newname)}

Sets the receiver object’s name to the string \texttt{newname}.

\textbf{Example}:

\begin{verbatim}
points=.array~of("N","S","E","W")
say points~objectName /* (no change yet) Says: "an Array" */
points~objectName="(compass)" /* Changes obj name POINTS to "compass"*/
say points~objectName /* Shows new obj name. Says: "compass" */
say points~defaultName /* Default is still available. */
/* Says "an Array" */
##
\end{verbatim}
Chapter 5. The Builtin Classes

5.1.1.17. request

```rexx
>>-request(classid)--------------------------------------------><
```

Returns an object of the `classid` class, or the Nil object if the request cannot be satisfied.

This method first compares the identity of the object’s class (see the `id` method of the Class class in [id]) to `classid`. If they are the same, the receiver object is returned as the result. Otherwise, `request` tries to obtain and return an object satisfying `classid` by sending the receiver object the conversion message `make` with the string `classid` appended (converted to uppercase). For example, a `request("string")` message causes a `makeString` message to be sent. If the object does not have the required conversion method, `request` returns the Nil object.

The conversion methods cause objects to produce different representations of themselves. The presence or absence of a conversion method defines an object’s capability to produce the corresponding representations. For example, lists can represent themselves as arrays, because they have a `makeArray` method, but they cannot represent themselves as directories, because they do not have a `makeDirectory` method. Any conversion method must return an object of the requested class. For example, `makeArray` must return an array. The language processor uses the `makeString` method to obtain string values in certain contexts; see Required String Values.

5.1.1.18. run

```rexx
>>-run(method+--------------------------------+-)--------------><
```

Runs the method object `method` (see The Method Class). The `method` has access to the object variables of the receiver object, as if the receiver object had defined the method by using `setMethod`.

If you specify the Individual or Array option, any remaining `arguments` are arguments for the method.
(You need to specify only the first letter; all characters following the first character are ignored.)

Individual

Passes any remaining arguments to the method as arguments in the order you specify them.

Array

Requires `argument`, which is an array object. (See The Array Class.) The member items of the array are passed to the method as arguments. The first argument is at index 1, the second argument at
index 2, and so on. If you omitted any indexes when creating the array, the corresponding arguments are omitted when passing the arguments.

If you specify neither Individual nor Array, the method runs without arguments.

The method argument can be a string containing a method source line instead of a method object. Alternatively, you can pass an array of strings containing individual method lines. In either case, run creates an equivalent method object.

Notes:

1. The run method is a private method. See Public versus Private Methods for information private method restrictions.
2. The RUN method is a protected method.

5.1.1.19. send

```
+---------------+
 V               |
 >>-send(messagename---+-----------+-+-)-----------------------><
 ++,argument--+
```

Returns a result of invoking a method on the target object using the specified messagename and arguments. The send() method allows methods to be invoked using dynamically constructed method names.

The messagename can be a string or an array. If messagename is an array object, its first item is the name of the message and its second item is a class object to use as the starting point for the method search. For more information, see Classes and Inheritance.

Any arguments are passed to the receiver as arguments for messagename in the order you specify them.

Example:

```
world=.WorldObject~new
// the following 3 calls are equivalent
msg1=world~hello("Fred")
msg2=world~send("HELLO", "Fred")
msg3=.message~new(world,"HELLO", "i", "Fred")~-send

say msg1~result /* Produces Hello Fred 21:04:25.065000 */
    /* for example */
say msg2~result /* Produces Hello Fred 21:04:25.081000 */
    /* for example */
say msg3~result /* Produces Hello Fred 21:04:25.101000 */
    /* for example */
```

::class 'WorldObject' public
::method hello
    use arg name
    return "Hello" name time('L')
5.1.1.20. sendWith

```
>>-sendWith(messagename,arguments)----------------------------------><
```

Returns a result of invoking a method on the target object using the specified message name and arguments. The send() method allows methods to be invoked using dynamically constructed method names and arguments.

The `messagename` can be a string or an array. If `messagename` is an array object, its first item is the name of the message and its second item is a class object to use as the starting point for the method search. For more information, see Classes and Inheritance.

The `arguments` argument must be a single-dimension array instance. The values contained in `arguments` are passed to the receiver as arguments for `messagename` in the order you specify them.

Example:

```ooRexx
world=.WorldObject~new
// the following 3 calls are equivalent
msg1=world~hello("Fred")
msg2=world~sendWith("HELLO", .array~of("Fred"))
msg3=.message~new(world,"HELLO", "A", .array~of("Fred"))~~send
```

```ooRexx
say msg1~result /* Produces Hello Fred 21:04:25.065000 */
/* for example */
say msg2~result /* Produces Hello Fred 21:04:25.081000 */
/* for example */
say msg3~result /* Produces Hello Fred 21:04:25.101000 */
/* for example */
```

```ooRexx
::class 'WorldObject' public
::method hello
  use arg name
  return "Hello" name time('L')
```

5.1.1.21. setMethod

```
>>>-setMethod(methodname-----------------+--)------------------><
```

Adds a method to the receiver object’s collection of object methods. The `methodname` is the name of the new method. This name is translated to uppercase. If you previously defined a method with the same name using `setMethod`, the new method replaces the earlier one. If you omit `method`, `setMethod` makes the method name `methodname` unavailable for the receiver object. In this case, sending a message of that name to the receiver object runs the `unknown` method (if any).

The `method` can be a string containing a method source line instead of a method object. Or it can be an array of strings containing individual method lines. In either case, `setMethod` creates an equivalent method object.
Chapter 5. The Builtin Classes

The third parameter describes if the method that is attached to an object should have object or float scope. "Float" scope means that it shares the same scope with methods that were defined outside of a class. "Object" scope means it shares the scope with other, potentially statically defined, methods of the object it is attached to.

Notes:

1. The setMethod method is a private method. See the setPrivate method in setPrivate for details.
2. The setMethod method is a protected method.

5.1.1.22. start

```
+---------------+    
V                |
>>-start(messagename---+-----------+-+-)-----------------------><
 +-,argument-+
```

Returns a message object (see The Message Class) and sends it a start message to start concurrent processing. The object receiving the message messagename processes this message concurrently with the sender’s continued processing.

The messagename can be a string or an array. If messagename is an array object, its first item is the name of the message and its second item is a class object to use as the starting point for the method search. For more information, see Classes and Inheritance.

Any arguments are passed to the receiver as arguments for messagename in the order you specify them.

When the receiver object has finished processing the message, the message object retains its result and holds it until the sender requests it by sending a result message. For further details, see start.

Example:

```ruby
world=.WorldObject~new
msg1=world~start("HELLO") /* same as next line */
msg2=.message~new(world,"HELLO")~"start" /* same as previous line */

say msg1~result /* Produces Hello world 21:04:25.065000 */
/* for example */
say msg2~result /* Produces Hello world 21:04:25.081000 */
/* for example */

::class 'WorldObject' public
::method hello
  return "Hello world" time('L')
```

5.1.1.23. startWith

```
>>-startWith(messagename,arguments)------------------------------->
```
Returns a message object (see The Message Class) and sends it a start message to start concurrent processing. The object receiving the message messagename processes this message concurrently with the sender’s continued processing.

The messagename can be a string or an array. If messagename is an array object, its first item is the name of the message and its second item is a class object to use as the starting point for the method search. For more information, see Classes and Inheritance.

The arguments argument must be a single-dimension array instance. Any values contained in arguments are passed to the receiver as arguments for messagename in the order you specify them.

When the receiver object has finished processing the message, the message object retains its result and holds it until the sender requests it by sending a result message. For further details, see start.

Example:

```rexx
world=.WorldObject~new
msg1=world~startWith("HELLO", .array~of("Fred") /* same as next line */
msg2=.message~new(world,"HELLO", 'i', .array~of("Fred"))~start /* same as previous line */

say msg1~result /* Produces Hello Fred 21:04:25.065000 */
/* for example */
say msg2~result /* Produces Hello Fred 21:04:25.081000 */
/* for example */
```

::class 'WorldObject' public
::method hello
  use arg name
  return "Hello" name time('L')

5.1.1.24. string

>>>-string---------------------------------------------<

Returns a human-readable string representation of the object. The exact form of this representation depends on the object and might not alone be sufficient to reconstruct the object. All objects must be able to produce a string representation of themselves in this way.

The object’s string representation is obtained from the objectName method (which can in turn use the defaultName method). See also the objectName method (OBJECTNAME) and the defaultName method (defaultName).

The distinction between this method, the makeString method (which obtains string values—see makeString) and the request method (see request) is important. All objects have a string method, which returns a string representation (human-readable form) of the object. This form is useful in tracing and debugging. Only those objects that have information with a meaningful string form have a makeString method to return this value. For example, directory objects have a readable string representation (a Directory), but no string value, and, therefore, no makeString method.

Of the classes that Rexx provides, only the String class has a makeString method. Any subclasses of the String class inherit this method by default, so these subclasses also have string values. Any other class can also provide a string value by defining a makeString method.
Chapter 5. The Built-in Classes

5.1.1.25. unsetMethod

>>-unsetMethod(methodname)<-------------------------------------><

Cancels the effect of all previous setMethod for method methodname. It also removes any method methodname introduced with enhanced when the object was created. If the object has received no setMethod method, no action is taken.

Notes:

1. The unsetMethod method is a private method. See the setPrivate method in setPrivate for details.
2. The unsetMethod method is a protected method.

5.1.2. The Class Class

The Class class is like a factory that produces the factories that produce objects. It is a subclass of the Object class. The instance methods of the Class class are also the class methods of all classes.
Figure 5-2. The Class class and methods

<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class</td>
</tr>
</tbody>
</table>

= \= \== < > >>
baseClass
defaultName
define
delete
enhanced
id
inherit
isSubclassOf
metaClass
method
methods
mixinClass
new
queryMixinClass
subClass
subClasses
superClass
superClasses
unInherit

5.1.2.1. Inherited Methods

Methods inherited from the Object class.

new (class method) instanceMethod send
= \= \== < > >> instanceMethods sendWith
 class isa sendWith
 copy isInstanceOf start
defaultName objectName startWith
hasMethod objectName= string
identityHash Request unsetMethod
init Run
5.1.2.2. baseClass

Returns the base class associated with the class. If the class is a mixin class, the base class is the first superclass that is not also a mixin class. If the class is not a mixin class, the base class is the class receiving the baseClass message.

5.1.2.3. defaultName

Returns a short human-readable string representation of the class. The string returned is of the form

The id class

where id is the identifier assigned to the class when it was created.

Examples:

```plaintext
say .array~defaultName /* Displays "The Array class" */
say .account~defaultName /* Displays "The ACCOUNT class" */
say .savings~defaultName /* Displays "The Savings class" */
```

```plaintext
::class account /* Name is all upper case */
::class "Savings" /* String name is mixed case */
```

5.1.2.4. define

Incorporates the method object method in the receiver class’s collection of instance methods. The method name methodname is translated to to uppercase. Using the define method replaces any existing definition for methodname in the receiver class.

If you omit method, the method name methodname is made unavailable for the receiver class. Sending a message of that name to an instance of the class causes the unknown method (if any) to be run.

The method argument can be a string containing a method source line instead of a method object. Alternatively, you can pass an array of strings containing individual method lines. Either way, define creates an equivalent method object.

Notes:

1. The classes Rexx provides do not permit changes or additions to their method definitions.
2. The define method is a protected method.

Example:

```plaintext
bank_account=.object~subclass("Account")
```
bank_account`define("TYPE","return "a bank account"")

**5.1.2.5. delete**

```
>>-delete(methodname)----------------------------------------------------->
```

Removes the receiver class's definition for the method name *methodname*. If the receiver class defined *methodname* as unavailable with the **define** method, this definition is nullified. If the receiver class had no definition for *methodname*, no action is taken.

**Notes:**

1. The classes Rexx provides do not permit changes or additions to their method definitions.
2. **delete** deletes only methods the target class defines. You cannot delete inherited methods the target's superclasses define.
3. The **delete** method is a protected method.

**Example:**

```rexx
myclass=.object~subclass("Myclass") /* After creating a class */
myclass`define("TYPE","return "my class"") /* and defining a method */
myclass`delete("TYPE") /* this deletes the method */
```

**5.1.2.6. enhanced**

```
>>-enhanced(methods+-------------+-)-------------------------------------->
   | +-----------+ |
   | V           | |
   +---,argument---+
```

Returns an enhanced new instance of the receiver class, with object methods that are the instance methods of the class, enhanced by the methods in the collection *methods*. The collection indexes are the names of the enhancing methods, and the items are the method objects (or strings or arrays of strings containing method code). (See the description of **define**.) You can use any collection that supports a **supplier** method.

**enhanced** sends an **init** message to the created object, passing the *arguments* specified on the **enhanced** method.

**Example:**

```rexx
/* Set up rclass with class method or methods you want in your */
/* remote class */
rclassmeths = .directory~new

rclassmeths["DISPATCH"] = d_source /* d_source must have code for a */
   /* DISPATCH method. */

/* The following sends init("Remote Class") to a new instance */
rclass=.class~enhanced(rclassmeths,"Remote Class")
```
Chapter 5. The Builtin Classes

5.1.2.7. id

>>-id---------------------------------------------------------->>

Returns the class identity (instance) string. (This is the string that is an argument on the subClass and mixinClass methods.) The string representations of the class and its instances contain the class identity.

Example:

myobject=.object~subClass("my object") /* Creates a subclass */
say myobject~id /* Produces: "my object" */

5.1.2.8. inherit

>>-inherit(classobj-+-----------+-)----------------------------><

+-,classpos+-

Causes the receiver class to inherit the instance and class methods of the class object classobj. The classpos is a class object that specifies the position of the new superclass in the list of superclasses. (You can use the superClasses method to return the immediate superclasses.)

The new superclass is inserted in the search order after the specified class. If the classpos class is not found in the set of superclasses, an error is raised. If you do not specify classpos, the new superclass is added to the end of the superclasses list.

Inherited methods can take precedence only over methods defined at or above the base class of the classobj in the class hierarchy. Any subsequent change to the instance methods of classobj takes immediate effect for all the classes that inherit from it.

The new superclass classobj must be created with the mixinClass option of the ::CLASS directive or the mixinClass method and the base class of the classobj must be a direct superclass of the receiver object. The receiver must not already descend from classobj in the class hierarchy and vice versa.

The method search order of the receiver class after inherit is the same as before inherit, with the addition of classobj and its superclasses (if not already present).

Notes:

1. You cannot change the classes that Rexx provides by sending inherit messages.
2. The inherit method is a protected method.

Example:

room~inherit(.location)

5.1.2.9. isSubClassOf

>>-isSubclassOf(class)-------------------------------------><

...
Returns .true ("1") if the object is a subclass of the specified class. Returns .false ("0") if the object is not a subclass of the specified class. A class is a subclass of a class if the target class is the same as class or if class is in the object’s direct or mixin class inheritance chain. For example:

```
.String~isSubclassOf(.object) -> 1
.String~isSubclassOf(.mutablebuffer) -> 0
```

### 5.1.2.10. metaClass

```-metaClass--------------------------------------------------><```

Returns the receiver class’s default metaclass. This is the class used to create subclasses of this class when you send `subClass` or `mixinClass` messages (with no metaclass arguments). The instance methods of the default metaclass are the class methods of the receiver class. For more information about class methods, see Object Classes. See also the description of the `subClass` method in `subClass`.

### 5.1.2.11. method

```-method(methodname)------------------------------------------><```

Returns the method object for the receiver class’s definition for the method name `methodname`. If the receiver class defined `methodname` as unavailable, this method returns the Nil object. If the receiver class did not define `methodname`, an error is raised.

**Example:**

```/
/* Create and retrieve the method definition of a class */
myclass=.object~subClass("My class") /* Create a class */
method=.method~new("","Say arg(1)") /* Create a method object */
myclass~define("ECHO",method) /* Define it in the class */
method_source = myclass~method("ECHO")~source /* Extract it */
say method_source /* Says “an Array” */
say method_source[1] /* Shows the method source code */
```

### 5.1.2.12. methods

```-methods-+----------------+----------------------------------><```

Returns a Supplier object for all the instance methods of the receiver class and its superclasses, if you specify no argument. If `class_object` is the Nil object, `methods` returns a supplier object for only the instance methods of the receiver class. If you specify a `class_object`, this method returns a supplier object containing only the instance methods that `class_object` defines. The supplier enumerates all the names and methods existing at the time of the supplier’s creation.
Note: Methods that have been hidden with a setMethod or define method are included with the other methods that methods returns. The hidden methods have the Nil object for the associated method.

Example:

```rexx
objsupp=.object~methods
do while objsupp~available
  say objsupp~index -- displays all instance method
  objsupp~next -- names of the Object class
end
```

5.1.2.13. mixinClass

```rexx
>>-mixinClass(classid-+-------------------------+-)------------><
   ++,metaclass-+----------+-+
   ++,methods-+
```

Returns a new mixin subclass of the receiver class. You can use this method to create a new mixin class that is a subclass of the superclass to which you send the message. The classid is a string that identifies the new mixin subclass. You can use the id method to retrieve this string.

The metaclass is a class object. If you specify metaclass, the new subclass is an instance of metaclass. (A metaclass is a class that you can use to create a class, that is, a class whose instances are classes. The Class class and its subclasses are metaclasses.)

If you do not specify a metaclass, the new mixin subclass is an instance of the default metaclass of the receiver class. For subclasses of the Object class, the default metaclass is the Class class.

The methods is a collection whose indexes are the names of methods and whose items are method objects (or strings or arrays of strings containing method code). If you specify methods, the new class is enhanced with class methods from this collection. (The metaclass of the new class is not affected.)

The metaClass method returns the metaclass of a class.

The method search order of the new subclass is the same as that of the receiver class, with the addition of the new subclass at the start of the order.

Example:

```rexx
buyable=.object~mixinClass("Buyable") /* New subclass is buyable */
   /* Superclass is Object class */
```

5.1.2.14. new

```rexx
>>-new-+---------------+---------------------------------------><
   |     +-,-,----+ |
   |      V       |
   |+-(----arg----++)++
```
Chapter 5. The Builtin Classes

Returns a new instance of the receiver class, whose object methods are the instance methods of the class. This method initializes a new instance by running its `init` methods. (See Initialization.) `new` also sends an `init` message. If you specify args, `new` passes these arguments on the `init` message.

Example:

```
/* new method example */
a = .account~new -- Object variable balance=0
y = .account~new(340.78) -- Object variable balance=340.78

::class account subclass object
::method init /* Report time each account created */
    /* plus free toaster oven */
    Expose balance
    Arg opening_balance
    Say "Creating" self~objectName "at time" time()
    If datatype(opening_balance, "N") then balance = opening_balance
    else balance = 0
    If balance > 100 then Say " You win a free toaster oven"
```

5.1.2.15. `queryMixinClass`

`>>-queryMixinClass---------------------------------------------><`

Returns 1 (true) if the class is a mixin class, or 0 (false).

5.1.2.16. `subclass`

`>>-subclass(classid-+-------------------------+-)--------------><`

Returns a new subclass of the receiver class. You can use this method to create a new class that is a subclass of the superclass to which you send the message. The `classid` is a string that identifies the subclass. (You can use the `id` method to retrieve this string.)

The `metaclass` is a class object. If you specify `metaclass`, the new subclass is an instance of `metaclass`. (A metaclass is a class that you can use to create a class, that is, a class whose instances are classes. The `Class` class and its subclasses are metaclasses.)

If you do not specify a `metaclass`, the new subclass is an instance of the default metaclass of the receiver class. For subclasses of the `Object` class, the default metaclass is the `Class` class.

The `methods` is a collection whose indexes are the names of methods and whose items are method objects (or strings or arrays of strings containing method code). If you specify `methods`, the new class is enhanced with class methods from this collection. (The metaclass of the new class is not affected.)

The `metaclass` method returns the metaclass of a class.

The method search order of the new subclass is the same as that of the receiver class, with the addition of the new subclass at the start of the order.
Chapter 5. The Built-in Classes

Example:

```rxx
room=.object~subclass("Room") /* Superclass is .object */
    /* Subclass is room */
    /* Subclass identity is Room */
```

5.1.2.17. subclasses

```
>>-subclasses----------------------------------------------->
```

Returns the immediate subclasses of the receiver class in the form of a single-index array of the required size, in an unspecified order. (The program should not rely on any order.)

5.1.2.18. superClass

```
>>-superClass----------------------------------------------->
```

Returns the immediate superclass of the receiver class. The immediate superclass is the original class used on a subClass or a mixinClass method. For the Object Class, superClass returns .Nil.

Example:

```rxx
say .object~superclass -- displays "The Nil object"
say .class~superclass -- displays "The Object class"
say .set~superclass -- displays "The Table class"
```

5.1.2.19. superClasses

```
>>-superClasses----------------------------------------------->
```

Returns the immediate superclasses of the receiver class in the form of a single-index array of the required size. The immediate superclasses are the original class used on a subClass or a mixinClass method, plus any additional superclasses defined with the inherit method. The array is in the order in which the class has inherited the classes. The original class used on a subClass or mixinClass method is the first item of the array.

Example:

```rxx
z=.class~superClasses
/* To obtain the information this returns, you could use: */
do i over z
    say i
end
```

5.1.2.20. uninherit

```
>>-uninherit(classobj)----------------------------------------->
```

ooRexx Reference Version 4.0.0
Nullifies the effect of any previous `inherit` message sent to the receiver for the class `classobj`.

**Note:** You cannot change the classes that Rexx provides by sending `uninherit` messages.

Example:

```plaintext
location=.object~mixinClass("Location")
room=.object~subclass("Room")~"inherit(location) /* Creates subclass */
    /* and specifies inheritance */
room~uninherit(location)
```

### 5.1.3. The String Class

String objects represent character-string data values. A character string value can have any length and contain any characters.
Chapter 5. The Builtin Classes

Figure 5-3. The String class and methods

<table>
<thead>

</tr>
</tbody>
</table>

Note: The String class also has available class methods that its metaclass, the Class class, defines.
5.1.3.1. Inherited Methods

Methods inherited from the Object class.

- new (class method)
- = \= \== \<= \<= \>= \>=
- instanceMethod
- send
- instanceMethods
- sendWith
- class
- isA
- setMethod
- copy
- isInstanceOf
- start
- defaultName
- objectName
- startWith
- hasMethod
- objectName=
- string
- identityHash
- Request
- unsetMethod
- init
- Run

Methods inherited from the Comparable class.

- compareTo

5.1.3.2. new (Class Method)

>>-new(stringvalue)--------------------------------------------><

Returns a new string object initialized with the characters in stringvalue.

5.1.3.3. Arithmetic Methods

>>-arithmetic_operator(argument)-------------------------------><

Note: The syntax diagram above is for the non-prefix operators. The prefix + and argument.

Returns the result of performing the specified arithmetic operation on the receiver object. The receiver object and the argument must be valid numbers (see Numbers). The arithmetic_operator can be:

- Addition
- Subtraction
- Multiplication
- Division
- Integer division (divide and return the integer part of the result)
- Remainder (divide and return the remainder—not modulo, because the result can be negative)
- Exponentiation (raise a number to a whole-number power)
- Prefix - Same as the subtraction: 0 - number
- Prefix + Same as the addition: 0 + number

See Numbers and Arithmetic for details about precision, the format of valid numbers, and the operation rules for arithmetic. Note that if an arithmetic result is shown in exponential notation, it might have been rounded.
Chapter 5. The Builtin Classes

Examples:

5+5  ->  10
8-5  ->  3
5*2  ->  10
6/2  ->  3
9/4  ->  1
9\4  ->  2
2**3 ->  8

+5   ->  5  /* Prefix + */
-5   -> -5  /* Prefix - */

5.1.3.4. Comparison Methods

>>-comparison_operator(argument)-------------------------------><

Returns 1 (true) or 0 (false), the result of performing the specified comparison operation. The receiver object and the argument are the terms compared. Both must be string objects. If argument is not a string object, it is converted to its string representation for the comparison. The one exception is when argument is the Nil object for the ==, \==, =, \=, >, <, and <> operators. A string object will never compare equal to the Nil object, even when the string matches the string value of the Nil object ("The Nil object").

The comparison operators you can use in a message are:

= True if the terms are equal (for example, numerically or when padded)
\=, >, <, <> True if the terms are not equal (inverse of =)
> Greater than
< Less than
>\= Greater than or equal to
\< Not less than
<= Less than or equal to
\> Not greater than

Examples:

5=5  ->  1  /* equal */
42\=41 ->  1  /* All of these are */
42>\=41 ->  1  /* "not equal" */
42<41  ->  1
13>\12 ->  1  /* Variations of */
12<\13 ->  1  /* less than and */
13=\12 ->  1  /* greater than */
12\<\13 ->  0
12\=\13 ->  1
12\>\13 ->  1
All strict comparison operations have one of the characters doubled that define the operator. The == and \== operators check whether two strings match exactly. The two strings must be identical (character by character) and of the same length to be considered strictly equal.

The strict comparison operators such as >> or <= carry out a simple character-by-character comparison. There is no padding of either of the strings being compared. The comparison of the two strings is from left to right. If one string is shorter than and a leading substring of another, then it is smaller than (less than) the other. The strict comparison operators do not attempt to perform a numeric comparison on the two operands.

For all the other comparison operators, if both terms are numeric, the String class does a numeric comparison (ignoring, for example, leading zeros—see Numeric Comparisons). Otherwise, it treats both terms as character strings, ignoring leading and trailing whitespace characters and padding the shorter string on the right with blanks.

Character comparison and strict comparison operations are both case-sensitive, and for both the exact collating order can depend on the character set. In an ASCII environment, the digits are lower than the alphabetic characters, and lowercase alphabetic characters are higher than uppercase alphabetic characters.

The strict comparison operators you can use in a message are:

- == True if terms are strictly equal (identical)
- \== True if the terms are NOT strictly equal (inverse of ==)
- >> Strictly greater than
- << Strictly less than
- >>= Strictly greater than or equal to
- <= Strictly NOT less than
- <<= Strictly less than or equal to
- >>= Strictly NOT greater than

Examples:

- "space"=="space" -> 1 /* Strictly equal */
- "space"\==" space" -> 1 /* Strictly not equal */
- "space">>" space" -> 1 /* Variations of */
- " space"<<="space" -> 1 /* strictly greater */
- "space">>=" space" -> 1 /* than and less than */
- "space"\<<=" space" -> 1
- " space"<<=" space" -> 1
- " space">>=" space" -> 1

5.1.3.5. Logical Methods

>>-logical_operator(argument)----------------------------------><
Note: For NOT (prefix \), omit the parentheses and argument.

Returns 1 (true) or 0 (false), the result of performing the specified logical operation. The receiver object and the argument are character strings that evaluate to 1 or 0.

The logical_operator can be:

&  AND (Returns 1 if both terms are true.)
|  Inclusive OR (Returns 1 if either term or both terms are true.)
&& Exclusive OR (Returns 1 if either term, but not both terms, is true.)
Prefix \ Logical NOT (Negates; 1 becomes 0, and 0 becomes 1.)

Examples:

1&0  ->  0
1|0  ->  1
1&&0  ->  1
\1  ->  0

5.1.3.6. Concatenation Methods

concatenation_operator(argument)----------------------------><

Concatenates the receiver object with argument. (See String Concatenation.) The concatenation_operator can be:

" "  concatenates without an intervening blank. The abuttal operator "" is the null string. The language processor uses the abuttal to concatenate two terms that another operator does not separate.
\  concatenates without an intervening blank.
" "  concatenates with one blank between the receiver object and the argument. (The operator " " is a blank.)

Examples:

f = "abc"
f"def"  ->  "abcdef"
" |||"def"  ->  "abcdef"
f "def"  ->  "abc def"

5.1.3.7. abbrev

abbrev(info+---------+-)-----------------------------------><

+-,length+-
Returns 1 if info is equal to the leading characters of the receiving string and the length of info is not less than length. Returns 0 if either of these conditions is not met.

If you specify length, it must be a positive whole number or zero. The default for length is the number of characters in info.

Examples:

"Print"~abbrev("Pri")   -> 1
"PRINT"~abbrev("Pri")   -> 0
"PRINT"~abbrev("PRI",4)  -> 0
"PRINT"~abbrev("PRY")   -> 0
"PRINT"~abbrev(""")     -> 1
"PRINT"~abbrev("",1)    -> 0

Note: A null string always matches if a length of 0, or the default, is used. This allows a default keyword to be selected automatically if desired.

Example:

say "Enter option:"; pull option.
select /* keyword1 is to be the default */
  when "keyword1"~abbrev(option) then ...
  when "keyword2"~abbrev(option) then ...
  ...
  otherwise nop;
end;

5.1.3.8. abs

Returns the absolute value of the receiving string. The result has no sign and is formatted according to the current NUMERIC settings.

Examples:

12.3`abs     ->  12.3
"-0.307"`abs -> 0.307

5.1.3.9. b2x

Returns a string, in character format, that represents the receiving binary string converted to hexadecimal.

The receiving string is a string of binary (0 or 1) digits. It can be of any length. It can optionally include whitespace characters (at 4-digit boundaries only, not leading or trailing). These are to improve readability and are ignored.
Chapter 5. The Builtin Classes

The returned string uses uppercase alphabetic characters for the values A-F and does not include whitespace.

If the receiving binary string is a null string, \texttt{b2x} returns a null string. If the number of binary digits in the receiving string is not a multiple of four, up to three 0 digits are added on the left before the conversion to make a total that is a multiple of four.

\textbf{Examples:}

\begin{verbatim}
"11000011"~b2x    ->    "C3"
"10111"~b2x       ->    "17"
"101"~b2x         ->    "5"
"1 1111 0000"~b2x ->    "1F0"
\end{verbatim}

You can combine \texttt{b2x} with the methods \texttt{x2d} and \texttt{x2c} to convert a binary number into other forms.

\textbf{Example:}

\begin{verbatim}
"10111"~b2x~x2d    ->    "23"  /* decimal 23 */
\end{verbatim}

\textbf{5.1.3.10. bitAnd}

\begin{verbatim}
>>-bitAnd-<--------------------------------------------------------<
    +-,(string-------+-)++
    +-+,pad+-
\end{verbatim}

Returns a string composed of the receiver string and the argument \textit{string} logically ANDed together, bit by bit. (The encodings of the strings are used in the logical operation.) The length of the result is the length of the longer of the two strings. If you omit the \texttt{pad} character, the AND operation stops when the shorter of the two strings is exhausted, and the unprocessed portion of the longer string is appended to the partial result. If you provide \texttt{pad}, it extends the shorter of the two strings on the right before the logical operation. The default for \textit{string} is the zero-length (null) string.

\textbf{Examples:}

\begin{verbatim}
"12"x~bitAnd        ->    "12"x
"73"x~bitAnd("27"x) ->    "23"x
"13"x~bitAnd("5555"x) ->    "1155"x
"13"x~bitAnd("5555"x,"74"x) ->    "1154"x
"pQrS"~bitAnd(,"DF"x) ->    "PQRS"  /* ASCII */
\end{verbatim}

\textbf{5.1.3.11. bitOr}

\begin{verbatim}
>>-bitOr-<--------------------------------------------------------<
    +-,(string-------+-)++
    +-+,pad+-
\end{verbatim}

Returns a string composed of the receiver string and the argument \textit{string} logically inclusive-ORed, bit by bit. The encodings of the strings are used in the logical operation. The length of the result is the length of the longer of the two strings. If you omit the \texttt{pad} character, the OR operation stops when the shorter of the two strings is exhausted, and the unprocessed portion of the longer string is appended to the partial
result. If you provide `pad`, it extends the shorter of the two strings on the right before the logical operation. The default for `string` is the zero-length (null) string.

**Examples:**

```
"12"x~bitOr -> "12"x
"15"x~bitOr("24"x) -> "35"x
"15"x~bitOr("2456"x) -> "3556"x
"15"x~bitOr("2456"x,"F0"x) -> "35F6"x
"1111"x~bitOr(,"4D"x) -> "5D5D"x
"pQrS"~bitOr(,"20"x) -> "pqrs" /* ASCII */
```

### 5.1.3.12. bitXor

```
>-bitXor<-----------------------------------------------------+-
 +-(string-+------+-)-+
 |-,pad-+

Returns a string composed of the receiver string and the argument `string` logically exclusive-ORed, bit by bit. The encodings of the strings are used in the logical operation. The length of the result is the length of the longer of the two strings. If you omit the `pad` character, the XOR operation stops when the shorter of the two strings is exhausted, and the unprocessed portion of the longer string is appended to the partial result. If you provide `pad`, it extends the shorter of the two strings on the right before carrying out the logical operation. The default for `string` is the zero-length (null) string.

**Examples:**

```
"12"x~bitXor -> "12"x
"12"x~bitXor("22"x) -> "30"x
"1211"x~bitXor("22"x) -> "3011"x
"1111"x~bitXor("444444"x) -> "555544"x
"1111"x~bitXor("444444"x,"40"x) -> "555504"x
"1111"x~bitXor(,"4D"x) -> "5C5C"x
"C711"x~bitXor("222222"x," ") -> "E53302"x /* ASCII */
```

### 5.1.3.13. c2d

```
>-c2d<-----------------------------------------------------+-
 +-(n)-+

Returns the decimal value of the binary representation of the receiving string. If the result cannot be expressed as a whole number, an error results. That is, the result must not have more digits than the current setting of NUMERIC DIGITS. If you specify `n`, it is the length of the returned result. If you do not specify `n`, the receiving string is processed as an unsigned binary number. If the receiving string is null, C2D returns 0.

**Examples:**

```
"09"X~c2d -> 9
"81"X~c2d -> 129
```
Chapter 5. The Builtin Classes

"FF81"X~c2d -> 65409
"="~c2d -> 0
"a"~c2d -> 97 /* ASCII */

If you specify n, the receiving string is taken as a signed number expressed in n characters. The number is positive if the leftmost bit is off, and negative if the leftmost bit is on. In both cases, it is converted to a whole number, which can therefore be negative. The receiving string is padded on the left with "00"x characters (not "sign-extended"), or truncated on the left to n characters. This padding or truncation is as though receiving_string~right(n,'00') had been processed. If n is 0, c2d always returns 0.

Examples:

"81"X~c2d(1) -> -127
"81"X~c2d(2) -> 129
"FF81"X~c2d(2) -> -127
"FF81"X~c2d(1) -> -127
"FF7F"X~c2d(1) -> 127
"F081"X~c2d(2) -> -3967
"F081"X~c2d(1) -> -127
"0031"X~c2d(0) -> 0

5.1.3.14. c2x

Returns a string, in character format, that represents the receiving string converted to hexadecimal. The returned string contains twice as many bytes as the receiving string. On an ASCII system, sending a c2x message to the receiving string 1 returns 31 because "31"X is the ASCII representation of 1.

The returned string has uppercase alphabetic characters for the values A-F and does not include whitespace. The receiving string can be of any length. If the receiving string is null, c2x returns a null string.

Examples:

"0123"X~c2x -> "0123" /* "30313233"X in ASCII */
"ZD8"~c2x -> "5A4438" /* "3541343338"X in ASCII */

5.1.3.15. caselessAbbrev

Returns 1 if info is equal to the leading characters of the receiving string and the length of info is not less than length. Returns 0 if either of these conditions is not met. The characters are tested using a caseless comparison.

If you specify length, it must be a positive whole number or zero. The default for length is the number of characters in info.

Examples:
Chapter 5. The Builtin Classes

"Print"~caselessAbbrev("Pri") -> 1
"PRINT"~caselessAbbrev("Pri") -> 1
"PRINT"~caselessAbbrev("PRI",4) -> 0
"PRINT"~caselessAbbrev("PRY") -> 0
"PRINT"~caselessAbbrev(""") -> 1
"PRINT"~caselessAbbrev(""",1) -> 0

Note: A null string always matches if a length of 0, or the default, is used. This allows a default keyword to be selected automatically if desired.

Example:

say "Enter option:"; parse pull option .
select /* keyword1 is to be the default */
  when "keyword1"~caselessAbbrev(option) then ... 
  when "keyword2"~caselessAbbrev(option) then ... 
  ... 
  otherwise nop; 
end;

5.1.3.16. caselessChangeStr

\[\text{caselessChangeStr(needle,newneedle)}\]

Returns a copy of the receiver object in which \textit{newneedle} replaces occurrences of \textit{needle}. If \textit{count} is not specified, all occurrences of \textit{needle} are replaced. If \textit{count} is specified, it must be a positive, whole number that gives the maximum number of occurrences to be replaced. The \textit{needle} searches are performed using caseless comparisons.

Here are some examples:

"AbaAbb"~caselessChangeStr("A","") -> "bbb"
AbaBabAB~changeStr("ab","xy") -> "xyxyxyxy"
AbaBabAB~changeStr("ab","xy",1) -> "xyaBabAB"

5.1.3.17. caselessCompare

\[\text{caselessCompare(string)}\]

Returns 0 if the argument \textit{string} is identical to the receiving string using a caseless comparison. Otherwise, returns the position of the first character that does not match. The shorter string is padded on the right with \textit{pad} if necessary. The default \textit{pad} character is a blank.

Examples:

"abc"~caselessCompare("ABC") -> 0
5.1.3.18. caselessCompareTo

```
"abc" - caselessCompare("Ak")  ->  2
"ab " - caselessCompare("AB")  ->  0
"AB " - caselessCompare("ab"," ")  ->  0
"ab " - caselessCompare("ab","x")  ->  3
"abXX " - caselessCompare("ab","x")  ->  5
```

Performs a caseless sort comparison of the target string to the string argument. If the two strings are equal, 0 is returned. If the target string is larger, 1 is returned. -1 if the string argument is the larger string. The comparison is performed starting at character n for length characters in both strings. n must be a positive whole number. If n is omitted, the comparison starts at the first character. length must be a non-negative whole number. If omitted, the comparison will take place to the end of the target string.

Examples:

```
"abc" - caselessCompareTo("abc")  ->  0
"b" - caselessCompareTo("a")  ->  1
"a" - caselessCompareTo("b")  ->  -1
"abc" - caselessCompareTo("abc")  ->  0
"aBc" - caselessCompareTo("abc")  ->  0
"000abc000" - caselessCompareTo(111abc111", 4, 3)  ->  0
```

5.1.3.19. caselessCountStr

```
\> caselessCountStr(needle)--------------------------------------------><
```

Returns a count of the occurrences of needle in the receiving string that do not overlap. All matches are made using caseless comparisons.

Here are some examples:

```
"a0Aa0A" - caselessCountStr("a")  ->  4
"J0kKk0" - caselessCountStr("KK")  ->  1
```

5.1.3.20. caselessEquals

```
\> caselessEquals(other)-----------------------------------------------><
```

Returns .true ("1") if the target string is strictly equal to the other string, using a caseless comparison. Returns .false ("0") if the two strings are not strictly equal. Examples:

```
"a" - caselessEquals("A")  ->  1
"aa" - caselessEquals("A")  ->  0
"4" - caselessEquals("3")  ->  0
```

142          ooRexx Reference Version 4.0.0
5.1.3.21. caselessLastPos

```plaintext
>>-caselessLastPos(needle-+---------------------------+-)---><
  +-,--+-------+--+---------+-+
  +-start-+ +-,length-+
```

Returns the position of the last occurrence of a string, `needle`, in the receiving string. (See also POS.) It returns 0 if `needle` is the null string or not found. By default, the search starts at the last character of the receiving string and scans backward to the beginning of the string. You can override this by specifying `start`, the point at which the backward scan starts and `length`, the range of characters to scan. The `start` must be a positive whole number and defaults to `receiving_string~length` if larger than that value or omitted. The `length` must be a non-negative whole number and defaults to `start`. The search is performed using caseless comparisons.

**Examples:**

```
"abc def ghi"~caselessLastPos(" ") -> 8
"abcdefg"~caselessLastPos(" ") -> 0
"efgxyz"~caselessLastPos("XY") -> 4
"abc def ghi"~caselessLastPos(" ",7) -> 4
"abc def ghi"~caselessLastPos(" ",7,3) -> 0
```

5.1.3.22. caselessMatch

```plaintext
>>-caselessMatch(start,other-+----------------------------+-)-------------------><
  +-,--+---+--+---------+-+
  +n-+ +-,length-+
```

Returns .true ("1") if the characters of the `other` match the characters of the target string beginning at position `start`. Return .false ("0") if the characters are not a match. The matching is performed using caseless comparisons. `start` must be a positive whole number less than or equal to the length of the target string.

If `n` is specified, the match will be performed starting with character `n` of `other`. The default value for `n` is "1". `n` must be a positive whole number less than or equal to the length of `other`.

If `length` is specified, it defines a substring of `other` that is used for the match. `length` must be a positive whole number and the combination of `n` and `length` must be a valid substring within the bounds of `other`.

The caselessMatch method is useful for efficient string parsing as it does not require new string objects be extracted from the target string.

**Examples:**

```
"Saturday"~caselessMatch(6, "day")    -> 1
"Saturday"~caselessMatch(6, "DAY")   -> 1
"Saturday"~caselessMatch(6, "SUNDAY", 4, 3) -> 1
"Saturday"~caselessMatch(6, "daytime", 1, 3) -> 1
```
5.1.3.23. caselessMatchChar

```plaintext
>>-caselessMatchChar(n,chars)-------------------------><
```

Returns .true ("1") if the character at position \( n \) matches any character of the string \( \text{chars} \). Returns .false ("0") if the character does not match any of the characters in the reference set. The match is made using caseless comparisons. The argument \( n \) must be a positive whole number less than or equal to the length of the target string.

**Examples:**

```
"a+b"~caselessMatchChar(2, "+-*/")  \rightarrow  1
"a+b"~caselessMatchChar(1, "+-*/")  \rightarrow  0
"Friday"~caselessMatchChar(3, "aeiou")  \rightarrow  1
"FRIDAY"~caselessMatchChar(3, "aeiou")  \rightarrow  1
```

5.1.3.24. caselessPos

```plaintext
>>-caselessPos(needle-+---------------------------+-)---><
```

+-,+--------+-,+----------+-,+-+
+-,start+-,+-,length+-

Returns the position in the receiving string of another string, \( \text{needle} \). (See also caselessLastPos.) It returns 0 if \( \text{needle} \) is the null string or is not found or if \( \text{start} \) is greater than the length of the receiving string. The search is performed using caseless comparisons. By default, the search starts at the first character of the receiving string (that is, the value of \( \text{start} \) is 1), and continues to the end of the string. You can override this by specifying \( \text{start} \), the point at which the search starts, and \( \text{length} \), the bounding limit for the search. If specified, \( \text{start} \) must be a positive whole number and \( \text{length} \) must be a non-negative whole number.

**Examples:**

```
"Saturday"~caselessPos("DAY")  \rightarrow  6
"abc def ghi"~caselessPos("x")  \rightarrow  0
"abc def ghi"~caselessPos(" ")  \rightarrow  4
"abc def ghi"~caselessPos(" ",5)  \rightarrow  8
"abc def ghi"~caselessPos(" ",5,3)  \rightarrow  0
```

5.1.3.25. caselessWordPos

```plaintext
>>-caselessWordPos(phrase-+--------+-)---------------------------------><
```

+-,start-+

Returns the word number of the first word of \( \text{phrase} \) found in the receiving string, or 0 if \( \text{phrase} \) contains no words or if \( \text{phrase} \) is not found. Word matches are made independent of case. Several whitespace characters between words in either \( \text{phrase} \) or the receiving string are treated as a single blank for the comparison, but, otherwise, the words must match exactly.

By default the search starts at the first word in the receiving string. You can override this by specifying \( \text{start} \) (which must be positive), the word at which the search is to be started.

**Examples:**
5.1.3.26. center/centre

Returns a string of length length with the receiving string centered in it. The pad characters are added as necessary to make up length. The length must be a positive whole number or zero. The default pad character is blank. If the receiving string is longer than length, it is truncated at both ends to fit. If an odd number of characters are truncated or added, the right-hand end loses or gains one more character than the left-hand end.

**Note:** To avoid errors because of the difference between British and American spellings, this method can be called either center or centre.

Examples:

```
abc~center(7) -> " ABC "
abc~CENTER(8,"-" ) -> "---ABC---"
"The blue sky"~centre(8) -> "e blue s"
"The blue sky"~centre(7) -> "e blue 
```

5.1.3.27. changeStr

```
Returns a copy of the receiver object in which newneedle replaces occurrences of needle. If count is not specified, all occurrences of needle are replaced. If count is specified, it must be a positive, whole number that gives the maximum number of occurrences to be replaced.
```

Here are some examples:

```
101100~changeStr("1",""") -> "000"
101100~changeStr("1","X") -> "X0XX00"
101100~changeStr("1","X",1) -> "X01100"
```
Chapter 5. The Builtin Classes

5.1.3.28. compare

\[\text{compare} \quad \text{string}\rightarrow\text{n, pad}\]

Returns 0 if the argument \textit{string} is identical to the receiving string. Otherwise, returns the position of the first character that does not match. The shorter string is padded on the right with \textit{pad} if necessary. The default \textit{pad} character is a blank.

\textbf{Examples:}
\begin{verbatim}
"abc"~compare("abc") -> 0
"abc"~compare("ak") -> 2
"ab"~compare("ab") -> 0
"ab "~compare("ab"," ") -> 0
"ab "~compare("ab","x") -> 3
"ab-- "~compare("ab","-") -> 5
\end{verbatim}

5.1.3.29. compareTo

\[\text{compareTo} \quad \text{string}\rightarrow\text{n, length}\]

Performs a sort comparison of the target string to the \textit{string} argument. If the two strings are equal, 0 is returned. If the target string is larger, 1 is returned. -1 if the \textit{string} argument is the larger string. The comparison is performed starting at character \textit{n} for \textit{length} characters in both strings. \textit{n} must be a positive whole number. If \textit{n} is omitted, the comparison starts at the first character. \textit{length} must be a non-negative whole number. If omitted, the comparison will take place to the end of the target string.

\textbf{Examples:}
\begin{verbatim}
"abc"~compareTo("abc") -> 0
"b"~compareTo("a") -> 1
"a"~compareTo("b") -> -1
"abc"~compareTo("aBc") -> 1
"aBc"~compareTo("abc") -> -1
"000abc000"~compareTo("111abc111", 4, 3) -> 0
\end{verbatim}

5.1.3.30. copies

\[\text{copies(n)}\]

Returns \textit{n} concatenated copies of the receiving string. The \textit{n} must be a positive whole number or zero.

\textbf{Examples:}
\begin{verbatim}
"abc"~copies(3) -> "abcabcabc"
"abc"~copies(0) -> ""
\end{verbatim}
5.1.3.31. countStr

```
>>>-countStr(needle)--------------------------------------------><

Returns a count of the occurrences of needle in the receiving string that do not overlap.

Here are some examples:

"101101"-countStr("1")   ->   4
"J0KKK0"-CountStr("KK")   ->   1
```

5.1.3.32. d2c

```
>>>-d2c+-+-------------------------------------------------><
  +-(n)-+

Returns a string, in character format, that is the ASCII representation of the receiving string, a decimal number. If you specify n, it is the length of the final result in characters; leading blanks are added to the returned string. The n must be a positive whole number or zero.

The receiving string must not have more digits than the current setting of NUMERIC DIGITS.

If you omit n, the receiving string must be a positive whole number or zero, and the result length is as needed. Therefore, the returned result has no leading "00"x characters.

Examples:

"65"-d2c   ->   "A"      /* "41"x is an ASCII "A" */
"65"-d2c(1)   ->   "A"
"65"-d2c(2)   ->   " A"
"65"-d2c(5)   ->   " A"
"109"-d2c   ->   "m"      /* "6D"x is an ASCII "m" */
"-109"-d2c(1)   ->   "δ"      /* "93"x is an ASCII "δ" */
"76"-d2c(2)   ->   "L"      /* "4C"x is an ASCII "L" */
"-180"-d2c(2)   ->   " L"

Implementation maximum: The returned string must not have more than 250 significant characters, although a longer result is possible if it has additional leading sign characters ("00"x and "FF"x).
```

5.1.3.33. d2x

```
>>>-d2x+-+-------------------------------------------------><
  +-(n)-+

Returns a string, in character format, that represents the receiving string, a decimal number converted to hexadecimal. The returned string uses uppercase alphabetic characters for the values A-F and does not include whitespace.

The receiving string must not have more digits than the current setting of NUMERIC DIGITS.
Chapter 5. The Built-in Classes

If you specify \( n \), it is the length of the final result in characters. After conversion the returned string is sign-extended to the required length. If the number is too big to fit into \( n \) characters, it is truncated on the left. If you specify \( n \), it must be a positive whole number or zero.

If you omit \( n \), the receiving string must be a positive whole number or zero, and the returned result has no leading zeros.

Examples:

\[
\begin{align*}
"9" \d2x & \rightarrow "9" \\
"129" \d2x & \rightarrow "81" \\
"129" \d2x(1) & \rightarrow "1" \\
"129" \d2x(2) & \rightarrow "81" \\
"129" \d2x(4) & \rightarrow "0081" \\
"257" \d2x(2) & \rightarrow "01" \\
"-127" \d2x(2) & \rightarrow "81" \\
"-127" \d2x(4) & \rightarrow "FF81" \\
"12" \d2x(0) & \rightarrow "" \\
\end{align*}
\]

Implementation maximum: The returned string must not have more than 500 significant hexadecimal characters, although a longer result is possible if it has additional leading sign characters (0 and F).

5.1.3.34. \texttt{dataType}

\texttt{>>-dataType-+-+-------------------------------><}  
\texttt{+-+type-++}

Returns \texttt{NUM} if you specify no argument and the receiving string is a valid Rexx number that can be added to 0 without error. It returns \texttt{CHAR} if the receiving string is not a valid number.

If you specify \texttt{type}, it returns 1 if the receiving string matches the type. Otherwise, it returns 0. If the receiving string is null, the method returns 0 (except when the \texttt{type} is \texttt{X} or \texttt{B}, for which \texttt{dataType} returns 1 for a null string). The following are valid \texttt{types}. You need to specify only the capitalized letter, or the number of the last type listed. The language processor ignores all characters surrounding it.

Alphanumeric

returns 1 if the receiving string contains only characters from the ranges a-z, A-Z, and 0-9.

Binary

returns 1 if the receiving string contains only the characters 0 or 1, or whitespace. Whitespace characters can appear only between groups of 4 binary characters. It also returns 1 if string is a null string, which is a valid binary string.

Lowercase

returns 1 if the receiving string contains only characters from the range a-z.

Mixed case

returns 1 if the receiving string contains only characters from the ranges a-z and A-Z.
Number
returns 1 if receiving_string~dataType returns NUM.

Logical
returns 1 if the receiving string is exactly "0" or "1". Otherwise it returns 0.

Symbol
returns 1 if the receiving string is a valid symbol, that is, if SYMBOL(string) does not return BAD. (See Symbols.) Note that both uppercase and lowercase alphabetic characters are permitted.

Uppercase
returns 1 if the receiving string contains only characters from the range A-Z.

Variable
returns 1 if the receiving string could appear on the left-hand side of an assignment without causing a SYNTAX condition.

Whole number
returns 1 if the receiving string is a whole number under the current setting of NUMERIC DIGITS.

Hexadecimal
returns 1 if the receiving string contains only characters from the ranges a-f, A-F, 0-9, and whitespace characters (as long as whitespace characters appear only between pairs of hexadecimal characters). Also returns 1 if the receiving string is a null string.

9 Digits
returns 1 if receiving_string~dataType("W") returns 1 when NUMERIC DIGITS is set to 9.

Examples:

```
" 12 "~dataType   ->   "NUM"
"**"~dataType     ->   "CHAR"
"123*"~dataType   ->   "CHAR"
"12.3"~dataType("N")  ->  1
"12.3"~dataType("W")    ->  0
"Fred"~dataType("M")   ->  1
"**"~dataType("M")     ->  0
"Fred"~dataType("L")   ->  0
"?20K"~dataType("s")  ->  1
"BCd3"~dataType("X")   ->  1
"BC d3"~dataType("X")  ->  1
"1"~dataType("O")     ->  1
"11"~dataType("O")    ->  0
```

Note: The dataType method tests the meaning or type of characters in a string, independent of the encoding of those characters (for example, ASCII or EBCDIC).
Chapter 5. The Builtin Classes

5.1.3.35. decodeBase64

>>-decodeBase64------------------------------------------------><

Returns a new string containing the decoded version of the base64 encoded receiving string. If the receiving string is not in base64 format then the returned result is undefined.

Examples:

"YWJjZGVm"~decodeBase64 -> "abcdef"

5.1.3.36. delStr

>>-delStr(n--+---------+--)------------------------------------><

Returns a copy of the receiving string after deleting the substring that begins at the n<sup>th</sup> character and is of length characters. If you omit length, or if length is greater than the number of characters from n to the end of string, the method deletes the rest of string (including the n<sup>th</sup> character). The length must be a positive whole number or zero. The n must be a positive whole number. If n is greater than the length of the receiving string, the method returns the receiving string unchanged.

Examples:

"abcd"~delStr(3) -> "ab"
"abcde"~delStr(3,2) -> "abe"
"abcde"~delStr(6) -> "abcde"

5.1.3.37. delWord

>>-delWord(n--+---------+--)-----------------------------------><

Returns a copy of the receiving string after deleting the substring that starts at the n<sup>th</sup> word and is of length blank-delimited words. If you omit length, or if length is greater than the number of words from n to the end of the receiving string, the method deletes the remaining words in the receiving string (including the n<sup>th</sup> word). The length must be a positive whole number or zero. The n must be a positive whole number. If n is greater than the number of words in the receiving string, the method returns the receiving string unchanged. The string deleted includes any whitespace characters following the final word involved but none of the whitespace characters preceding the first word involved.

Examples:

"Now is the time"~delWord(2,2) -> "Now time"
"Now is the time "~delWord(3) -> "Now is 
"Now is the time"~delWord(5) -> "Now is the time"
"Now is the time"~delWord(3,1) -> "Now is time"
5.1.3.38. encodeBase64

>>-encodeBase64----------------------------------------------------------><

Returns a new string that is the base64 encoded version of the receiving string.

Examples:

"abcdef"~encodeBase64 -> "YWJjZGVm"

5.1.3.39. equals

>>-equals(other)----------------------------------------------------------><

Returns .true ("1") if the target string is strictly equal to the other string. Returns .false ("0") if the two strings are not strictly equal. This is the same comparison performed by the "==" comparison method.

Examples:

"3"~equals("3") -> 1
"33"~equals("3") -> 0
"4"~equals("3") -> 0

5.1.3.40. format

>>-format-+----------------------------------------------------------><

Returns a copy of the receiving string, a number, rounded and formatted.

The number is first rounded according to standard Rexx rules, as though the operation receiving_string+0 had been carried out. If you specify no arguments the result of the method is the same as the result of this operation. If you specify any options, the number is formatted as described in the following.

The before and after options describe how many characters are to be used for the integer and decimal parts of the result. If you omit either or both of them, the number of characters for that part is as needed.

If before is not large enough to contain the integer part of the number (plus the sign for a negative number), an error results. If before is larger than needed for that part, the number is padded on the left with blanks. If after is not the same size as the decimal part of the number, the number is rounded (or extended with zeros) to fit. Specifying 0 causes the number to be rounded to an integer.

Examples:

"3"~format(4) -> " 3"
"1.73"~format(4,0) -> " 2"
"1.73"~format(4,3) -> " 1.730"
"-.76"~format(4,1) -> " -0.8"
Chapter 5. The Builtin Classes

"3.03" format(4) -> " 3.03"
" - 12.73" format(,4) -> "-12.7300"
" - 12.73" format -> "-12.73"
"0.000" format -> "0"

expp and expt control the exponent part of the result, which, by default, is formatted according to the current NUMERIC settings of DIGITS and FORM. expp sets the number of places for the exponent part; the default is to use as many as needed (which can be zero). expt specifies when the exponential expression is used. The default is the current setting of NUMERIC DIGITS.

If expp is 0, the number is not an exponential expression. If expp is not large enough to contain the exponent, an error results.

If the number of places needed for the integer or decimal part exceeds expt or twice expt, respectively, exponential notation is used. If expt is 0, exponential notation is always used unless the exponent would be 0. (If expp is 0, this overrides a 0 value of expt.) If the exponent would be 0 when a nonzero expp is specified, then expp+2 blanks are supplied for the exponent part of the result. If the exponent would be 0 and expp is not specified, the number is not an exponential expression.

Examples:

"12345.73" format(,2,2) -> "1.234573E+04"
"12345.73" format(,3,0) -> "1.235E+4"
"1.234573" format(,3,0) -> "1.235"
"1234567e5" format(,3,0) -> "123456700000.000"

5.1.3.41. hashCode

Returns a string value that is used as a hash value for MapCollection such as Table, Relation, Set, Bag, and Directory. The String hash code method will return the same hash value for all pairs of string instances for which the == operator is true. See hashCode Method for details.

5.1.3.42. insert

Returns a copy of the receiver string with the string new, padded or truncated to length length, inserted after the nth character. The default value for n is 0, which means insertion at the beginning of the string. If specified, n and length must be positive whole numbers or zero. If n is greater than the length of the receiving string, the string new is padded at the beginning. The default value for length is the length of new. If length is less than the length of the string new, then insert truncates new to length length. The default pad character is a blank.

Examples:
"abc"~insert("123") -> "123abc"
"abcdef"~insert(" ",3) -> "abc def"
"abc"~insert("123",5,6) -> "abc 123 "
"abc"~insert("123",5,6,"+") -> "abc++123+++"
"abc"~insert("123",5,6,"-") -> "123--abc"

5.1.3.43. lastPos

Returns the position of the last occurrence of a string, needle, in the receiving string. (See also POS.) It returns 0 if needle is the null string or not found. By default, the search starts at the last character of the receiving string and scans backward to the beginning of the string. You can override this by specifying start, the point at which the backward scan starts and length, the range of characters to scan. The start must be a positive whole number and defaults to receiving_string~length if larger than that value or omitted. The length must be a non-negative whole number and defaults to start.

Examples:

"abc def ghi"~lastPos(" ") -> 8
"abcdefghi"~lastPos(" ") -> 0
"efgxyz"~lastPos("xy") -> 4
"abc def ghi"~lastPos(" ",7) -> 4
"abc def ghi"~lastPos(" ",7,3) -> 0

5.1.3.44. left

Returns a string of length length, containing the leftmost length characters of the receiving string. The string returned is padded with pad characters (or truncated) on the right as needed. The default pad character is a blank. The length must be a positive whole number or zero. The left method is exactly equivalent to:

Examples:

"abc d""left(8) -> "abc d "
"abc d""left(8," ") -> "abc d..."
"abc def""left(7) -> "abc de"
5.1.3.45. length

Returns the length of the receiving string.

Examples:

```
"abcdefg" length  ->  8
"abc defg" length  ->  8
"" length  ->  0
```

5.1.3.46. lower

Returns a new string with the characters of the target string beginning with character \textit{n} for \textit{length} characters converted to lowercase. If \textit{n} is specified, it must be a positive whole number. If \textit{n} is not specified, the case conversion will start with the first character. If \textit{length} is specified, it must be a non-negative whole number. If \textit{length} the default is to convert the remainder of the string.

Examples:

```
"Albert Einstein" lower  ->  "albert einstein"
"ABCDEF" lower(4)  ->  "ABCdef"
"ABCDEF" lower(3,2)  ->  "ABcdEF"
```

5.1.3.47. makeArray

This method returns an array of strings containing the single lines that were separated using the \texttt{separator} string. The separator may be any string, including the null string. If the null string is used, an array containing each character of the string is returned. If the target string starts with the separator, the first array item will be a null string. If the string ends with a separator, no extra null string item will be added. The default separator is the newline character.

Example:

```
string = "hello".endofline"world".endofline"this is an array."
array = string'makeArray
say "the second line is:" array[2]  /* world */

string = "hello*world*this is an array."
array = string'makeArray("*")
say "the third line is:" array[3]  /* this is an array. */

string = "hello*world*this is an array.*"
array = string'makeArray("*")  /* contains 3 items */
```
5.1.3.48. makeString

Returns a string with the same string value as the receiver object. If the receiver is an instance of a subclass of the String class, this method returns an equivalent string object. If the receiver is a string object (not an instance of a subclass of the String class), this method returns the receiver object. See Required String Values.

5.1.3.49. match

Returns .true ("1") if the characters of the other match the characters of the target string beginning at position start. Return .false ("0") if the characters are not a match. start must be a positive whole number less than or equal to the length of the target string.

If n is specified, the match will be performed starting with character n of other. The default value for n is "1". n must be a positive whole number less than or equal to the length of other.

If length is specified, it defines a substring of other that is used for the match. length must be a positive whole number and the combination of n and length must be a valid substring within the bounds of other.

The match method is useful for efficient string parsing as it does not require new string objects be extracted from the target string.

Examples:

"Saturday" match(6, "day") -> 1
"Saturday" match(6, "DAY") -> 0
"Saturday" match(6, "Sunday", 4, 3) -> 1
"Saturday" match(6, "daytime", 1, 3) -> 1

5.1.3.50. matchChar

Returns .true ("1") if the character at position n matches any character of the string chars. Returns .false ("0") if the character does not match any of the characters in the reference set. The argument n must be a positive whole number less than or equal to the length of the target string.

Examples:

"a+b" matchChar(2, "+-*/") -> 1
"a+b" matchChar(1, "+-*/") -> 0
"Friday" matchChar(3, "aeiou") -> 1
"FRIDAY" matchChar(3, "aeiou") -> 0
5.1.3.51. max

Returns the largest number from among the receiver and any arguments. The number that `max` returns is formatted according to the current NUMERIC settings. You can specify any number of numbers.

Examples:

```
12`max(6,7,9) -> 12
17.3`max(19,17.03) -> 19
"-7"`max("-3","-4.3") -> -3
1`max(2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21) -> 21
```

5.1.3.52. min

Returns the smallest number from among the receiver and any arguments. The number that `min` returns is formatted according to the current NUMERIC settings. You can specify any number of numbers.

Examples:

```
12`min(6,7,9) -> 6
17.3`min(19,17.03) -> 17.03
"-7"`min("-3","-4.3") -> -7
21`min(20,19,18,17,16,15,14,13,12,11,10,9,8,7,6,5,4,3,2,1) -> 1
```

5.1.3.53. overlay

Returns a copy of the receiving string, which, starting at the \texttt{n}th character, is overlaid with the string \texttt{new}, padded or truncated to length \texttt{length}. The overlay can extend beyond the end of the receiving string. If you specify \texttt{length}, it must be a positive whole number or zero. The default value for \texttt{length} is the length of \texttt{new}. If \texttt{n} is greater than the length of the receiving string, padding is added before the \texttt{new} string. The default \texttt{pad} character is a blank, and the default value for \texttt{n} is 1. If you specify \texttt{n}, it must be a positive whole number.

Examples:

```
"abcdef"`overlay(" ",3) -> "ab def"
```
5.1.3.54. **pos**

```plaintext
>>-pos(needle-+---------------------------+-)---><
+-start++ ++,length++
```

Returns the position in the receiving string of another string, `needle`. (See also `lastPos`.) It returns 0 if `needle` is the null string or is not found or if `start` is greater than the length of the receiving string. By default, the search starts at the first character of the receiving string (that is, the value of `start` is 1), and continues to the end of the string. You can override this by specifying `start`, the point at which the search starts, and `length`, the bounding limit for the search. If specified, `start` must be a positive whole number and `length` must be a non-negative whole number.

**Examples:**

```
"Saturday"~pos("day")        ->  6
"abc def ghi"~pos("x")      ->  0
"abc def ghi"~pos(" ")     ->  4
"abc def ghi"~pos(" ",5)    ->  8
"abc def ghi"~pos(" ",5,3)  ->  0
```

5.1.3.55. **replaceAt**

```plaintext
>>-replaceAt(new,n,length-----)<-
+-,pad+-
```

Returns a copy of the receiving string, with the characters from the `n`th character for `length` characters replaced with `new`. The replacement position and length can extend beyond the end of the receiving string. The starting position, `n`, must be a positive whole number, and the `length` must be a positive whole number or zero. If `n` is greater than the length of the receiving string, padding is added before the `new` string. The default `pad` character is a blank.

**Examples:**

```
"abcdef"~replaceAt(" ",3, 1)  ->  "ab def"
"abcdef"~replaceAt(" ",3, 3)  ->  "ab f"
"abc"~replaceAt("123",5,6,"+") ->  "abc+123"
```

5.1.3.56. **reverse**

```plaintext
>>-reverse------------------------------------------>
```

Returns a copy of the receiving string reversed.
Chapter 5. The Builtin Classes

Examples:

"ABC."~reverse  ->  ".cBA"
"XYZ "~reverse  ->  " ZYX"

5.1.3.57. right

Returns a string of length length containing the rightmost length characters of the receiving string. The string returned is padded with pad characters, or truncated, on the left as needed. The default pad character is a blank. The length must be a positive whole number or zero.

Examples:

"abc d"~right(8)  ->  " abc d"
"abc def"~right(5)  ->  "c def"
"12"~right(5,"0")  ->  "00012"

5.1.3.58. sign

Returns a number that indicates the sign of the receiving string, which is a number. The receiving string is first rounded according to standard Rexx rules, as though the operation receiving_string+0 had been carried out. It returns -1 if the receiving string is less than 0, 0 if it is 0, and 1 if it is greater than 0.

Examples:

"12.3"~sign  ->  1
" -0.307"~sign  ->  -1
0.0~sign  ->  0

5.1.3.59. space

Returns a copy of receiving string, with n pad characters between each whitespace-delimited word. If you specify n, it must be a positive whole number or zero. If it is 0, all whitespace characters are removed. Leading and trailing whitespace characters are always removed. The default for n is 1, and the default pad character is a blank.

Examples:

"abc def "~space  ->  "abc def"
" abc def"~space(3)  ->  "abc def"
5.1.3.60. **strip**

```plaintext
>>-strip-+----------------------+-------------------------------><
  +-(option-+--------+-)-+
  +-,char-+
```

Returns a copy of the receiving string with leading characters, trailing characters, or both, removed, based on the `option` you specify. The following are valid `options`. (You need to specify only the first capitalized letter; all characters following it are ignored.)

- **Both**
  - Removes both leading and trailing characters. This is the default.
- **Leading**
  - Removes leading characters.
- **Trailing**
  - Removes trailing characters.

The `char` specifies the character to be removed, and the default is a blank. If you specify `char`, it must be exactly one character long.

**Examples:**

```plaintext
" ab c "~strip -> "ab c"
" ab c "~strip("L") -> "ab c ",
" ab c "~strip("t") -> " ab c",
"12.7000"~strip(,0) -> "12.7",
"0012.700"~strip(,0) -> "12.7"
```

5.1.3.61. **subchar**

```plaintext
>>-subchar(n)----------------------------------------------><
```

Returns the `n`'th character of the receiving string. `n` must be a positive whole number. If `n` is greater that the length of the receiving string then a zero-length string is returned.

5.1.3.62. **substr**

```plaintext
>>-substr(n-+--------------------------+-)----------------------><
  +-length-+ +-,pad-+
```

Returns a copy of the receiving string with leading characters, trailing characters, or both, removed, based on the `option` you specify. The following are valid `options`. (You need to specify only the first capitalized letter; all characters following it are ignored.)

- **Both**
  - Removes both leading and trailing characters. This is the default.
- **Leading**
  - Removes leading characters.
- **Trailing**
  - Removes trailing characters.

The `char` specifies the character to be removed, and the default is a blank. If you specify `char`, it must be exactly one character long.

**Examples:**

```plaintext
" ab c "~strip -> "ab c"
" ab c "~strip("L") -> "ab c ",
" ab c "~strip("t") -> " ab c",
"12.7000"~strip(,0) -> "12.7",
"0012.700"~strip(,0) -> "12.7"
```
Returns the substring of the receiving string that begins at the $n$th character and is of length $length$, padded with $pad$ if necessary. The $n$ must be a positive whole number. If $n$ is greater than $receiving_string\_length$, only pad characters are returned.

If you omit $length$, the rest of the string is returned. The default $pad$ character is a blank.

**Examples:**

```
"abc"~substr(2)   ->   "bc"
"abc"~substr(2,4) ->   "bc   
"abc"~substr(2,6,:) ->   "bc...."
```

**Note:** In some situations the positional (numeric) patterns of parsing templates are more convenient for selecting substrings, in particular if you need to extract more than one substring from a string. See also left and right.

### 5.1.3.63. subWord

```
>>-subWord(n--+-------------+-)<
  +-n-,length-+

Returns the substring of the receiving string that starts at the $n$th word and is up to $length$ blank-delimited words. The $n$ must be a positive whole number. If you omit $length$, it defaults to the number of remaining words in the receiving string. The returned string never has leading or trailing whitespace, but includes all whitespace characters between the selected words.

**Examples:**

```
"Now is the time"~subWord(2,2)   ->   "is the"
"Now is the time"~subWord(3)     ->   "the time"
"Now is the time"~subWord(5)     ->   ""
```

### 5.1.3.64. translate

```
>>-translate-+--------------------------------------------------------------------------+-
><
  +-tableo-+-------------------------+-+ +-,--+---+--+---------+-+
  +-tablei-+ +-,pad-+

Returns a copy of the receiving string with each character translated to another character or unchanged. You can also use this method to reorder the characters in the output table. (See last example)

The output table is $tableo$ and the input translation table is $tablei$. translate searches $tablei$ for each character in the receiving string. If the character is found, the corresponding character in $tableo$ is used in the result string. If there are duplicates in $tablei$, the first (leftmost) occurrence is used. If the character is
Chapter 5. The Builtin Classes

not found, the original character in the receiving string is used. The result string is always of the same
length as the receiving string.

The tables can be of any length. If you specify neither translation table and omit pad, the receiving string
is translated to uppercase (that is, lowercase a-z to uppercase A-Z), but if you include pad the entire string
is translated to pad characters. tablei defaults to XRANGE("00"x, "FF"x), and tableo defaults to the null
string and is padded with pad or truncated as necessary. The default pad is a blank.

n is the position of the first character of the translated range. The default starting position is 1. length is
the range of characters to be translated. If omitted, length remainder of the string from the starting
position to the end is used.

Examples:

"abcdef" translate             ->  "ABCDEF"
"abcdef" translate( , , 3, 2)   ->  "abCDef"
"abcdef" translate("12", "ec")  ->  "ab2df"
"abcdef" translate("12", "abcd", ")  ->  "12. ef"
"APQRV" translate(, "PR")      ->  "A Q V"
"APQRV" translate(XRANGE("00"x, "Q")) ->  "APQ "
"4123" translate("abcd", "1234")  ->  "dabc"
"4123" translate("abcd", "1234", , 2, 2)  ->  "4ab1"

Note: The last example shows how to use the translate method to reorder the characters in a string.
In the example, the last character of any 4-character string specified as the first argument would be
moved to the beginning of the string.

5.1.3.65. trunc

>>-trunc-+-----+-----------------------------------------------><
+-n-+->

Returns the integer part the receiving string, which is a number, and n decimal places. The default n is 0
and returns an integer with no decimal point. If you specify n, it must be a positive whole number or
zero. The receiving string is first rounded according to standard Rexx rules, as though the operation
receiving_string+0 had been carried out. This number is then truncated to n decimal places or trailing
zeros are added if needed to reach the specified length. The result is never in exponential form. If there
are no nonzero digits in the result, any minus sign is removed.

Examples:

12.3 trunc               ->  12
127.09782 trunc(3)       ->  127.097
127.1 trunc(3)           ->  127.100
127 trunc(2)             ->  127.00

Note: The number is rounded according to the current setting of NUMERIC DIGITS if necessary,
before the method processes it.
5.1.3.66. upper

Returns a new string with the characters of the target string beginning with character \( n \) for \( length \) characters converted to uppercase. If \( n \) is specified, it must be a positive whole number. If \( n \) is not specified, the case conversion will start with the first character. If \( length \) is specified, it must be a non-negative whole number. If \( length \) the default is to convert the remainder of the string.

**Examples:**

"Albert Einstein"~upper -> "ALBERT EINSTEIN"
"abcdef"~upper(4) -> "abcDEF"
"abcdef"~upper(3,2) -> "abCDef"

5.1.3.67. verify

Returns a number that, by default, indicates whether the receiving string is composed only of characters from \( reference \). It returns 0 if all characters in the receiving string are in \( reference \) or returns the position of the first character in the receiving string not in \( reference \).

The \( option \) can be either \texttt{Nomatch} (the default) or \texttt{Match}. (You need to specify only the first capitalized and highlighted letter; all characters following the first character are ignored)

If you specify \texttt{Match}, the method returns the position of the first character in the receiving string that is in \( reference \), or returns 0 if none of the characters are found.

The default for \( start \) is 1. Thus, the search starts at the first character of the receiving string. You can override this by specifying a different \( start \) point, which must be a positive whole number.

The default for \( length \) is the length of the string from \( start \) to the end of the string. Thus, the search proceeds to the end of the receiving string. You can override this by specifying a different \( length \), which must be a non-negative whole number.

If the receiving string is null, the method returns 0, regardless of the value of the \( option \). Similarly, if \( start \) is greater than \texttt{receiving_string~length}, the method returns 0. If \( reference \) is null, the method returns 0 if you specify \texttt{Match}. Otherwise, the method returns the \( start \) value.

**Examples:**

"123"~verify("1234567890") -> 0
"123"~verify("1234567890") -> 2
"AB4T"~verify("1234567890") -> 1
"AB4T"~verify("1234567890","M") -> 3
"AB4T"~verify("1234567890","N") -> 1
"1P3Q4"~verify("1234567890",,3) -> 4
"123"~verify("",N,2) -> 2
"ABCDE"~verify("",,3) -> 3
"AB3CD5"~verify("1234567890","M",4) -> 6
"ABCDEF"~verify("ABC","N",2,3) -> 4
"ABCDEF"~verify("ADEF","M",2,3) -> 4

5.1.3.68. word

>>-word(n)-----------------------------------------------------><

Returns the n\textsuperscript{th} whitespace-delimited word in the receiving string or the null string if the receiving string has fewer than n words. The n must be a positive whole number. This method is exactly equivalent to receiving_string~subWord(n,1).

Examples:

"Now is the time"~word(3) -> "the"
"Now is the time"~word(5) -> ""

5.1.3.69. wordIndex

>>-wordIndex(n)------------------------------------------------><

Returns the position of the first character in the n\textsuperscript{th} whitespace-delimited word in the receiving string. It returns 0 if the receiving string has fewer than n words. The n must be a positive whole number.

Examples:

"Now is the time"~wordIndex(3) -> 8
"Now is the time"~wordIndex(6) -> 0

5.1.3.70. wordLength

>>-wordLength(n)-----------------------------------------------><

Returns the length of the n\textsuperscript{th} whitespace-delimited word in the receiving string or 0 if the receiving string has fewer than n words. The n must be a positive whole number.

Examples:

"Now is the time"~wordLength(2) -> 2
"Now comes the time"~wordLength(2) -> 5
"Now is the time"~wordLength(6) -> 0

5.1.3.71. wordPos

>>-wordPos(phrase-+--------+-)---------------------------------><
+-,start+-
Chapter 5. The Builtin Classes

Returns the word number of the first word of phrase found in the receiving string, or 0 if phrase contains no words or if phrase is not found. Several whitespace characters between words in either phrase or the receiving string are treated as a single blank for the comparison, but, otherwise, the words must match exactly.

By default the search starts at the first word in the receiving string. You can override this by specifying start (which must be positive), the word at which the search is to be started.

Examples:

"now is the time"~wordPos("the")  ->  3
"now is the time"~wordPos("The")  ->  0
"now is the time"~wordPos("is the")  ->  2
"now is the time"~wordPos("is the")  ->  2
"now is the time"~wordPos("is time ")  ->  0
"To be or not to be"~wordPos("be")  ->  2
"To be or not to be"~wordPos("be",3)  ->  6

5.1.3.72. words

Returns the number of whitespace-delimited words in the receiving string.

Examples:

"Now is the time"~words  ->  4
" "~words  ->  0

5.1.3.73. x2b

Returns a string, in character format, that represents the receiving string, which is a string of hexadecimal characters converted to binary. The receiving string can be of any length. Each hexadecimal character is converted to a string of 4 binary digits. The receiving string can optionally include whitespace characters (at byte boundaries only, not leading or trailing) to improve readability; they are ignored.

The returned string has a length that is a multiple of four, and does not include any whitespace.

If the receiving string is null, the method returns a null string.

Examples:

"C3"~x2b  ->  "11000011"
"7"~x2b  ->  "0111"
"1 C1"~x2b  ->  "000111000001"

You can combine x2b with the methods d2x and c2x to convert numbers or character strings into binary form.

Examples:
"C3"x~c2x~x2b -> "11000011"
"129"~d2x~x2b -> "10000001"
"12"~d2x~x2b -> "1100"

5.1.3.74. x2c

Returns a string, in character format, that represents the receiving string, which is a hexadecimal string converted to character. The returned string is half as many bytes as the receiving string. The receiving string can be any length. If necessary, it is padded with a leading 0 to make an even number of hexadecimal digits.

You can optionally include whitespace in the receiving string (at byte boundaries only, not leading or trailing) to improve readability; they are ignored.

If the receiving string is null, the method returns a null string.

Examples:

"4865 6c6c 6f"~x2c -> "Hello" /* ASCII */
"3732 73"~x2c -> "72s" /* ASCII */

5.1.3.75. x2d

Returns the decimal representation of the receiving string, which is a string of hexadecimal characters. If the result cannot be expressed as a whole number, an error results. That is, the result must not have more digits than the current setting of NUMERIC DIGITS.

You can optionally include whitespace characters in the receiving string (at byte boundaries only, not leading or trailing) to improve readability; they are ignored.

If the receiving string is null, the method returns 0.

If you do not specify n, the receiving string is processed as an unsigned binary number.

Examples:

"0E"~x2d -> 14
"81"~x2d -> 129
"F81"~x2d -> 3969
"FF81"~x2d -> 65409
"46 30"x~x2d -> 240 /* ASCII */
"66 30"x~x2d -> 240 /* ASCII */

If you specify n, the receiving string is taken as a signed number expressed in n hexadecimal digits. If the leftmost bit is off, then the number is positive; otherwise, it is a negative number. In both cases it is converted to a whole number, which can be negative. If n is 0, the method returns 0.
Chapter 5. The Builtin Classes

If necessary, the receiving string is padded on the left with 0 characters (note, not "sign-extended"), or truncated on the left to \( n \) characters.

**Examples:**

- \"81\"~x2d(2) -> -127
- \"81\"~x2d(4) -> 129
- \"F081\"~x2d(4) -> -3967
- \"F081\"~x2d(3) -> 129
- \"F081\"~x2d(2) -> -127
- \"F081\"~x2d(1) -> 1
- \"0031\"~x2d(0) -> 0

5.1.4. The Method Class

The Method class creates method objects from Rexx source code. It is a subclass of the Object class.

**Figure 5-4. The Method class and methods**

```
<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Method</td>
</tr>
</tbody>
</table>

new
newFile
loadExternalMethod

isGuarded
isPrivate
isProtected
package
setGuarded
setPrivate
setProtected
setSecurityManager
setUnguarded
source
```

**Note:** The Method class also has available class methods that its metaclass, the Class class, defines.
5.1.4.1. Inherited Methods

Methods inherited from the Object class.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>new (class method)</td>
<td>instanceMethod send</td>
</tr>
<tr>
<td>= &lt;= &lt;= &lt;= &gt;&lt;</td>
<td>instanceMethods sendWith</td>
</tr>
<tr>
<td>class</td>
<td>isA setMethod</td>
</tr>
<tr>
<td>copy</td>
<td>isInstanceOf start</td>
</tr>
<tr>
<td>defaultName</td>
<td>objectName startWith</td>
</tr>
<tr>
<td>hasMethod</td>
<td>objectName= string</td>
</tr>
<tr>
<td>identityHash</td>
<td>Request unsetMethod</td>
</tr>
<tr>
<td>init</td>
<td>Run</td>
</tr>
</tbody>
</table>

5.1.4.2. new (Class Method)

```rxml
>>-new(name,source----------+-+-----------------<)
    +---, context---+
```

Returns a new instance of method class, which is an executable representation of the code contained in the `source`. The `name` is a string. The `source` can be a single string or an array of strings containing individual method lines.

The `context` allows the created method to inherit class and routine lookup scope from another source. If specified, `context` can be a Method object, a Routine object, a Package object, or the string "PROGRAMSCOPE". PROGRAMSCOPE is the default, and specifies that the newly created method will inherit the class and routine search scope from the caller of new method.

5.1.4.3. newFile (Class Method)

```rxml
>>-newFile(filename)-------------------<
```

Returns a new instance of method class, which is an executable representation of the code contained in the file `filename`. The `filename` is a string.

5.1.4.4. loadExternalMethod (Class Method)

```rxml
>>-loadExternalMethod(name,descriptor)----------------<
```

Resolves a native method in an external library package and returns a Method object instance that can used to call the external method. The `descriptor` is a string containing blank-delimited tokens that identify the location of the native method. function. The first token identifies the type of native function and must be "LIBRARY". The second token must identify the name of the external library. The external library is located using platform-specific mechanisms for loading libraries. For Unix-based systems, the library name is case-sensitive. The third token is optional and specifies the name of the method within the library package. If not specified, `name` is used. The method name is not case sensitive. If the target method cannot be resolved, .nil is returned.
Example:

```
method = .Method"loadExternalMethod(\"homeAddress=\", \'LIBRARY mylib setHomeAddress\')
```

### 5.1.4.5. isGuarded

```
>>>isGuarded
```

Returns true ("1") if the method is a Guarded method. Returns false ("0") for Unguarded methods.

### 5.1.4.6. isPrivate

```
>>>isPrivate
```

Returns true ("1") if the method is a Private method. Returns false ("0") for Public methods. See Public versus Private Methods for details on private method restrictions.

### 5.1.4.7. isProtected

```
>>>isProtected
```

Returns true ("1") if the method is a Protected method. Returns false ("0") for unprotected methods.

### 5.1.4.8. package

```
>>>package
```

Returns the Package class instance that defined the method instance. The package instance controls and defines the search order for classes and routines referenced by the method code.

### 5.1.4.9. setGuarded

```
>>>setGuarded
```

Specifies that the method is a guarded method that requires exclusive access to its scope variable pool to run. If the receiver is already guarded, a `setGuarded` message has no effect. Guarded is the default state for method objects.

### 5.1.4.10. setPrivate

```
>>>setPrivate
```

Specifies that a method is a private method. By default, method objects are created as public methods. See Public versus Private Methods for details on private method restrictions.
5.1.4.11. setProtected

Specifies that a method is a protected method. Method objects are not protected by default. (See The Security Manager for details.)

5.1.4.12. setSecurityManager

Replaces the existing security manager with the specified security_manager_object. If security_manager_object is omitted, any existing security manager is removed.

5.1.4.13. setUnguarded

Turns off the guard attribute of the method, allowing this method to run on an object even if another method has acquired exclusive access to the scope variable pool. Methods are unguarded by default.

A guarded method can be active for an object only when no other method requiring exclusive access to the object's variable pool is active in the same object. This restriction does not apply if an object sends itself a message to run a method and it already has exclusive use of the same object variable pool. In this case, the method runs immediately regardless of its guarded state.

5.1.4.14. source

Returns the method source code as a single-index array of source lines. If the source code is not available, source returns an array of zero items.

5.1.5. The Routine Class

The Routine class creates routine objects from Rexx source code. It is a subclass of the Object class.
Figure 5-5. The Routine class and methods

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Routine</td>
<td></td>
</tr>
</tbody>
</table>

- new
- newFile
- loadExternalRoutine
- call
- callWith
- package
- setSecurityManager
- source

**Note:** The Routine class also has available class methods that its metaclass, the Class class, defines.

### 5.1.5.1. Inherited Methods

Methods inherited from the Object class.

- new (class method)
- instanceMethod
- send
- ==
- IsA
- sendWith
- instanceMethods
- setMethod
- <=
- instanceOf
- start
- <=
- objectName
- startWith
- =>
- objectName=
- string
- <=
- Request
- unsetMethod
- init
- Run

### 5.1.5.2. new (Class Method)

```rexx
new(name, source---+--------+-+---+---+)------+
+--+-, context+-+
```

Returns a new instance of the routine class, which is an executable representation of the code contained in the `source`. The `name` is a string. The `source` can be a single string or an array of strings containing
individual method lines.

The context allows the created routine to inherit class and routine lookup scope from another source. If specified, context can be a Method object, a Routine object, or a Package object. If not specified, the newly created method will inherit the class and routine search scope from the caller of new method.

5.1.5.3. newFile (Class Method)

```
>>-newFile(filename)------------------------------------------>>
```

Returns a new instance of the routine class, which is an executable representation of the code contained in the file filename. The filename is a string.

5.1.5.4. loadExternalRoutine (Class method)

```
>>-loadExternalRoutine(name,descriptor)------------------------><
```

Resolves a native routine in an external library package and returns a Routine object instance that can used to call the external routine. The descriptor is a string containing blank-delimited tokens that identify the location of the native routine, function. The first token identifies the type of native routine and must be "LIBRARY". The second token must identify the name of the external library. The external library is located using platform-specific mechanisms for loading libraries. For Unix-based systems, the library name is case-sensitive. The third token is optional and specifies the name of the routine within the library package. If not specified, name is used. The routine name is not case sensitive. If the target routine cannot be resolved, .nil is returned.

Example:

```
routine = .Routine~loadExternalRoutine("Pi", "LIBRARY rxmath RxCalcPi")
```

5.1.5.5. call

```
>>-call-+--------------------+------------------------------------><
```

Calls the routine object using the provided arguments. The code in the routine object is called as if it was an external routine call. The return value will be any value returned by the executed routine.

5.1.5.6. callWith

```
>>-call(array)----------------------------------------------------><
```

Calls the routine object using the arguments provided in array. Each element of array will be mapped to its corresponding call argument. The code in the routine object is called as if it was an external routine call. The return value will be any value returned by the executed routine.
5.1.5.7. package

\[\text{\textgreater\textgreater\textgreater \texttt{-package}}\]

Returns the Package class instance that defined the routine instance. The package instance controls and defines the search order for classes and routines referenced by the routine code.

5.1.5.8. setSecurityManager

\[\text{\textgreater\textgreater\textgreater \texttt{-setSecurityManager} \texttt{+-}}\]

Replaces the existing security manager with the specified \texttt{security_manager_object}. If \texttt{security_manager_object} is omitted, any existing security manager is removed.

5.1.5.9. source

\[\text{\textgreater\textgreater\textgreater \texttt{-source}}\]

Returns the routine source code as a single-index array of source lines. If the source code is not available, \texttt{source} returns an array of zero items.

5.1.6. The Package Class

The Package class contains the source code for a package of Rexx code. A package instance holds all of the routines, classes, and methods created from a source code unit and also manages external dependencies referenced by ::REQUIRES directives. The files loaded by ::REQUIRES are also contained in Package class instances. It is a subclass of the Object class.
Figure 5-6. The Package class and methods

```
Package

| new             |
| newFile         |
| addClass        |
| addPackage      |
| addPublicClass  |
| addPublicRoutine|
| addRoutine      |
| classes         |
| definedMethods  |
| findClass       |
| findRoutine     |
| importedClasses |
| importedPackages|
| loadLibrary     |
| loadPackage     |
| name            |
| publicClasses   |
| publicRoutines  |
| routines        |
| setSecurityManager|
| source          |
| sourceLine      |
| sourceSize      |
```

**Note:** The Package class also has available class methods that its metaclass, the Class class, defines.

### 5.1.6.1. Inherited Methods

Methods inherited from the Object class.

```
new (class method)  instanceMethod  send
=} = = = <= <> >>
class                instanceMethods sendWith
isA                  setMethod
```
5.1.6.2. new (Class Method)

```plaintext
>>>-new(name, source)------------------------------------------><
```

Returns a new instance of the package class, which is a representation of the code contained in the `source`. The `name` is a string. The `source` can be a single string or an array of strings containing individual method lines.

The third parameter influences the scope of the routine. If none is given, the program scope is used. If another method or routine object is specified, the scope of the provided method or routine is used.

5.1.6.3. newFile (Class Method)

```plaintext
>>>-newFile(filename)------------------------------------------><
```

Returns a new instance of the package class, which is an executable representation of the code contained in the file `filename`. The `filename` is a string.

5.1.6.4. addClass

```plaintext
>>>-addClass(name, class)----------------------------------------><
```

Adds the class object `class` to the available classes under the name `name`. This is added to the package as a non-public class.

5.1.6.5. addPackage

```plaintext
>>>-addPackage(package)----------------------------------------><
```

Adds the package object `package` to the dependent packages under the name `name`. The added package is processed as if it had been added using a `::REQUIRES` directive in the original package source.

5.1.6.6. addPublicClass

```plaintext
>>>-addPublicClass(name, class)----------------------------------><
```

Adds the class object `class` to the available public classes under the name `name`. This is added to the package as a public class.
5.1.6.7. **addPublicRoutine**

```>>-addPublicRoutine(name,routine)----------------------------------------><``

Adds the routine object `routin`e to the available routines under the name `name`. This is added to the package as a public routine.

5.1.6.8. **addRoutine**

```>>-addRoutine(name,routine)----------------------------------------><``

Adds the routine object `routin`e to the available routines under the name `name`. This is added to the package as a non-public routine.

5.1.6.9. **classes**

```>>-classes----------------------------------------------><``

Returns a directory containing all classes defined by this package or imported as public classes from another package.

5.1.6.10. **definedMethods**

```>>-definedMethods----------------------------------------------><``

Returns a directory containing all unattached methods defined by this package. This is the same directory available to code within the package via the .METHODS environment symbol.

5.1.6.11. **digits**

```>>-digits------------------------------------------------------><``

Returns the initial NUMERIC DIGITS setting used for all Rexx code contained within the package. The default value is 9. The ::OPTIONS directive can override the default value.

5.1.6.12. **findClass**

```>>-findClass(name)---------------------------------------------><``

Performs the standard environment symbol searches given class `name`. The search is performed using the same search mechanism used for environment symbols or class names specified on ::CLASS directives. If the name is not found, .nil will be returned.
5.1.6.13. findRoutine

```plaintext
>>>findRoutine(name)--------------------------------------------><
```

Searches for a routine within the package search order. This includes ::ROUTE directive within the package, public routines imported from other packages, or routines added using the addRoutine method. The argument `name` must be a string object. If the name is not found, .nil will be returned.

5.1.6.14. form

```plaintext
>>>form--------------------------------------------------------><
```

Returns the initial NUMERIC FORM setting used for all Rexx code contained within the package. The default value is SCIENTIFIC. The ::OPTIONS directive can override the default value.

5.1.6.15. fuzz

```plaintext
>>>fuzz--------------------------------------------------------><
```

Returns the initial NUMERIC FUZZ setting used for all Rexx code contained within the package. The default value is 0. The ::OPTIONS directive can override the default value.

5.1.6.16. importedClasses

```plaintext
>>>importedClasses--------------------------------------><
```

Returns a directory containing all public classes imported from other packages.

5.1.6.17. importedRoutines

```plaintext
>>>importedRoutines-------------------------------------><
```

Returns a directory containing all public routines imported from other packages.

5.1.6.18. loadLibrary

```plaintext
>>>loadLibrary(name)-----------------------------------------><
```

Loads a native library package and adds it to the list of libraries loaded by the interpreter. The `name` identifies a native external library file that will be located and loaded as if it had been named on a ::REQUIRES LIBRARY directive. If the library is successfully loaded, loadLibrary will return 1 (true), otherwise it returns 0 (false).
5.1.6.19. loadPackage

```ruby
>>-loadPackage(name+-+---------+-)----------------------------><
  +-,source+-+
```

Loads a package and adds it to the list of packages loaded by the package manager. If only `name` is specified, `name` identifies a file that will be located and loaded as if it had been named on a `::REQUIRES` directive. If `source` is given, it must be an array of strings that is the source for the loaded package. If a package `name` has already been loaded by the package manager, the previously loaded version will be used. The resolved package object will be added to the receiving package object's dependent packages.

5.1.6.20. name

```ruby
>>-name-------------------------------------------------><
```

Returns the string name of the package.

5.1.6.21. publicClasses

```ruby
>>-publicClasses--------------------------------------><
```

Returns a directory containing all public classes defined in this package.

5.1.6.22. publicRoutines

```ruby
>>-publicRoutines-------------------------------------><
```

Returns a directory containing all public routines defined in this package.

5.1.6.23. routines

```ruby
>>-routines-------------------------------------><
```

Returns a directory containing all routines defined in this package.

5.1.6.24. setSecurityManager

```ruby
>>-setSecurityManager+-+---------------------------+-----------><
  +(security_manager_object)++
```

Replaces the existing security manager with the specified `security_manager_object`. If `security_manager_object` is omitted, any existing security manager is removed.
5.1.6.25. source

\[\text{source} \] \<

Returns the package source code as a single-index array of source lines. If the source code is not available, `source` returns an array of zero items.

5.1.6.26. sourceLine

\[\text{sourceLine}(n) \] \<

Returns the \(n\)th source line from the package source. If the source code is not available or the indicated line does not exist, a null string is returned.

5.1.6.27. sourceSize

\[\text{sourceSize} \] \<

Returns the size of the source code for the package object. If the source code is not available, 0 is returned.

5.1.6.28. trace

\[\text{trace} \] \<

Returns the initial TRACE setting used for all Rexx code contained within the package. The default value is Normal. The `::OPTIONS` directive can override the default value.

5.1.7. The Message Class

A message object provides for the deferred or asynchronous sending of a message. You can create a message object by using the `new` method of the Message class or the `start` method of the Object class.
Chapter 5. The Builtin Classes

Figure 5-7. The Message class and methods

<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message</td>
</tr>
</tbody>
</table>

new

arguments
completed
errorCondition
hasError
messageName
notify
result
send
start
target

Note: The Message class also has available class methods that its metaclass, the Class class, defines.

5.1.7.1. Inherited Methods

Methods inherited from the Object class.

```
new (class method) instanceMethod send
= \= \== < > >>-
class instanceMethods sendWith
copy isA setMethod
defaultName isInstanceOf start
hasMethod objectName startWith
identityHash objectName= string
init Request unsetMethod
Run
```

5.1.7.2. new (Class Method)

```
>>-new(target,messagename-+-------------------------------+-)--><
| +---------------+ |
| V | |
| +-,Individual---+-----------+-+-+ |
| | +-,argument-+ |
```
Chapter 5. The Builtin Classes

+-,Array,argument-------------------+

Initializes the message object for sending the message name `messagename` to object `target`.

The `messagename` can be a string or an array. If `messagename` is an array object, its first item is the name of the message and its second item is a class object to use as the starting point for the method search. For more information, see Classes and Inheritance.

If you specify the Individual or Array option, any remaining arguments are arguments for the message.

(You need to specify only the first letter; all characters following the first are ignored.)

Individual

If you specify this option, specifying `argument` is optional. Any `arguments` are passed as message arguments to `target` in the order you specify them.

Array

If you specify this option, you must specify an `argument`, which is an array object. (See The Array Class.) The member items of the array are passed to `target` as arguments. The first argument is at index 1, the second argument at index 2, and so on. If you omitted any indexes when creating the array, the corresponding message arguments are also omitted.

If you specify neither Individual nor Array, the message sent has no arguments.

Note: This method does not send the message `messagename` to object `target`. The SEND or START method (described later) sends the message.

5.1.7.3. arguments

`>>>arguments`----------------------------------------------><

Returns an array of argument objects used to invoke the message.

5.1.7.4. completed

`>>>completed`----------------------------------------------><

Returns 1 if the message object has completed executing its message, or 0. You can use this method to test for completion as an alternative to calling `result` and waiting for the message to complete.

5.1.7.5. errorCondition

`>>>errorCondition`----------------------------------------------><

Returns an error condition object from any execution error with the message object’s message invocation. If the message completed normally, or is still executing, `errorCondition` returns the Nil object.
5.1.7.6. hasError

Returns 1 if the message object’s message was terminated with an error condition. Returns 0 if the message has not completed or completed without error.

5.1.7.7. messageName

Returns the string message name used to invoke a method.

5.1.7.8. notify

Requests notification about the completion of processing of the message send or start. The message object message is sent as the notification. You can use notify to request any number of notifications. After the notification message, you can use the result method to obtain any result from the messages send or start.

Example:

/* Event-driven greetings */

.prompter~new~prompt(.nil)

:class prompter

::method prompt

  expose name
  use arg msg

  if msg \= .nil then do
    name = msg~result
    if name = "quit" then return
    say "Hello," name
  end

  say 'Enter your name ("quit" to quit):

  /* Send the public default object .INPUT a LINEIN message asynchronously */

  msg=.message~new(.input,"LINEIN")~start

  /* Sends self~prompt(msg) when data available */

  msg~notify(.message~new(self,"PROMPT","I",msg))

  /* Don't leave until user has entered "quit" */

  guard on when name="quit"
5.1.7.9. result

Returns the result of the message send or start. If message processing is not yet complete, this method waits until it completes. If the message send or start raises an error condition, this method also raises an error condition.

Example:

/* Example using result method */
string=\"700\" /* Create a new string object, string */
bond=string\"start\"("reverse") /* Create a message object, bond, and */ /* start it. This sends a REVERSE */ /* message to string, giving bond */ /* the result. */

/* Ask bond for the result of the message */
say \"The result of message was\" bond\~result /* Result is 007 */

5.1.7.10. send

Returns the result (if any) of sending the message. If you specify target, this method sends the message to target. Otherwise, this method sends the message to the target you specified when the message object was created. send does not return until message processing is complete.

You can use the notify method to request notification that message processing is complete. You can use the result method to obtain any result from the message.

5.1.7.11. start

Sends the message to start processing at a specific target whereas the sender continues processing. If you specify target, this method sends the message to target. Otherwise, this method sends the message to the target you specified when the message object was created. This method returns as soon as possible and does not wait until message processing is complete. When message processing is complete, the message object retains any result and holds it until requested via the result method. You can use the notify method to request notification when message processing completes.

5.1.7.12. Example

/* Using Message class methods */
/* Note: In the following example, ::METHOD directives define class Testclass */
/* with method SHOWMSG */
ez=.testclass~new /* Creates a new instance of Testclass */
mymsg=ez~start("SHOWMSG","Hello, Ollie!",5) /* Creates and starts */
/* message mymsg to send */
/* SHOWMSG to ez */
/* Continue with main processing while SHOWMSG runs concurrently */
do 5
  say "Hello, Stan!"
end
/* Get final result of the SHOWMSG method from the mymsg message object */
say mymsg~result
say "Goodbye, Stan...
exit
::class testclass public /* Directive defines Testclass */
::method showmsg /* Directive creates new method SHOWMSG */
use arg text,reps /* class Testclass */
do reps
  say text
end
reply "Bye Bye, Ollie..."
return

The following output is possible:
Hello, Ollie!
Hello, Stan!
Hello, Ollie!
Hello, Stan!
Hello, Ollie!
Hello, Stan!
Hello, Ollie!
Hello, Stan!
Hello, Ollie!
Hello, Stan!
Hello, Ollie!
Hello, Stan!
Hello, Ollie!
Hello, Stan!
Bye Bye, Ollie...
Goodbye, Stan...

5.1.7.13. target

>>-target---------------------------------------------------><

Returns the object that is the target of the invoked message.
Chapter 5. The Builtin Classes

5.2. The Stream Classes

This section describes the Rexx classes which implement Rexx data streams.

5.2.1. The InputStream Class

This class is defined as an abstract mixin class. It must be implemented by subclassing it or inheriting from it as a mixin. Many of the methods in this class are abstract and must be overridden or they will throw a syntax error when invoked.

Figure 5-8. The InputStream class and methods

Note: The InputStream class also has available class methods that its metaclass, the Class class, defines.

5.2.1.1. Inherited Methods

Methods inherited from the Object class.

new (class method) instanceMethod send
\= \== \ !== < > <<
class instanceMethods sendWith
copy isa start
defaultName instanceof startWith
hasMethod objectName string
identityHash objectName= un泾setMethod
init Request Run

5.2.1.2. arrayIn
This is a default implementation of the arrayIn method using linein() method calls to fill the array.

5.2.1.3. charIn
This method is defined as an abstract method. Invoking it will cause syntax error 93.965 to be raised.

5.2.1.4. charOut
This is an unsupported operation for InputSteams. Invoking it will cause syntax error 93.963 to be raised.

5.2.1.5. chars
This method is defined as an abstract method. Invoking it will cause syntax error 93.965 to be raised.

5.2.1.6. close
This method is a NOP by default.

5.2.1.7. lineIn
This method is defined as an abstract method. Invoking it will cause syntax error 93.965 to be raised.

5.2.1.8. lineOut
This is an unsupported operation for InputSteams. Invoking it will cause syntax error 93.963 to be raised.

5.2.1.9. lines
This method is defined as an abstract method. Invoking it will cause syntax error 93.965 to be raised.

5.2.1.10. open
This method is a NOP method.

5.2.1.11. position
This method is an optionally supported operation. By default, it will cause syntax error 93.963 to be raised.
Chapter 5. The Built-in Classes

5.2.2. The OutputStream Class

This class is defined as an abstract mixin class. It must be implemented by subclassing it or inheriting from it as a mixin. Many of the methods in this class are abstract and must be overridden or they will throw a syntax error when invoked.

Figure 5-9. The OutputStream class and methods

```
Object

OutputStream

arrayOut  charIn  charOut  chars  close  lineIn  lineOut  lines  open  position
```

Note: The OutputStream class also has available class methods that its metaclass, the Class class, defines.

5.2.2.1. Inherited Methods

Methods inherited from the Object class.

```
new (class method)  instanceMethod  send
\= \== \=== \<> \>
class  instanceMethods  sendWith
copy  isa
defaultName  instanceOf  start
hasMethod  objectName  startWith
identityHash  objectName=  string
init  Request  unsetMethod
Run
```

5.2.2.2. arrayOut

This method is a default arrayOut implementation that writes all lines to the stream using lineout.
5.2.2.3. charIn
This is an unsupported operation for OutputSteams. Invoking it will cause syntax error 93.963 to be raised.

5.2.2.4. charOut
This method is defined as an abstract method. Invoking it will cause syntax error 93.965 to be raised.

5.2.2.5. chars
This is an unsupported operation for OutputSteams. Invoking it will cause syntax error 93.963 to be raised.

5.2.2.6. close
This method is a NOP by default.

5.2.2.7. lineln
This is an unsupported operation for OutputSteams. Invoking it will cause syntax error 93.963 to be raised.

5.2.2.8. lineOut
This method is defined as an abstract method. Invoking it will cause syntax error 93.965 to be raised.

5.2.2.9. lines
This is an unsupported operation for OutputSteams. Invoking it will cause syntax error 93.963 to be raised.

5.2.2.10. open
This method is a NOP by default.

5.2.2.11. position
This method is an optionally supported operation. By default, it will cause syntax error 93.963 to be raised.
5.2.3. The InputOutputStream Class

This class is defined as an abstract mixin class. It must be implemented by subclassing it or inheriting from it as a mixin. Many of the methods in this class are abstract and must be overridden or they will throw a syntax error when invoked.

Figure 5-10. The InputOutputStream class

```
Object
  + InputOutputStream
  + InputStream
  + OutputStream
```

Note: The InputOutputStream class also has available class methods that its metaclass, the Class class, defines.

5.2.3.1. Inherited Methods

Methods inherited from the Object class.

```
new (class method) instanceMethod send
<= == \== < > <=
class isA sendWith
copy isInstanceOf start
defaultName objectName startWith
hasMethod objectName= string
identityHash Request unsetMethod
init Run
```

Methods inherited from the InputStream class.

Note: This class is searched second for inherited methods.

```
arrayIn close open
charIn lineIn position
charOut lineOut
chars lines
```

Methods inherited from the OutputStream class.

Note: This class is searched first for inherited methods.
5.2.4. The Stream Class

A stream object allows external communication from Rexx. (See Input and Output Streams for a discussion of Rexx input and output.)

The Stream class is a subclass of the InputOutputStream class.

Figure 5-11. The Stream class and methods

<table>
<thead>
<tr>
<th>Object</th>

<tr>
<td>supplier</td>
</tr>
<tr>
<td>unInit</td>
</tr>
</tbody>
</table>

**Note:** The Stream class also has available class methods that its metaclass, the Class class, defines. It also inherits methods from the InputOutputStream class.
5.2.4.1. Inherited Methods

Methods inherited from the Object class.

- `new` (class method) instanceMethod send
- `=` `⇐` `⇐` `<` `⇐` `⇐` `⇐` `⇐` sendWith
- `class`
- `copy`
- `defaultName`
- `hasMethod`
- `identityHash`
- `init`
- `instanceMethods`
- `isA`
- `isInstanceOf`
- `objectName`
- `objectName=`
- `run`
- `setMethod`
- `start`
- `startWith`
- `string`
- `Request`
- `Run`
- `unsetMethod`

Methods inherited from the InputStream class.

Note: This class is searched second for inherited methods.

- `arrayIn`
- `close`
- `open`
- `charIn`
- `lineIn`
- `position`
- `charOut`
- `lineOut`
- `chars`
- `lines`

Methods inherited from the OutputStream class.

Note: This class is searched first for inherited methods.

- `arrayOut`
- `close`
- `open`
- `charIn`
- `lineIn`
- `position`
- `charOut`
- `lineOut`
- `chars`
- `lines`

5.2.4.2. new (Inherited Class Method)

`>>-new(name)--------------------------------------------------------------------------------<<`

Initializes a stream object for stream `name`, but does not open the stream. Returns the new stream object.

5.2.4.3. arrayIn

`++-(LINES)++`

`>>-arrayIn-+----------------------------------------><`

Returns a fixed array that contains the data of the stream in line or character format, starting from the current read position. The line format is the default.

If you have used the `charIn` method, the first line can be a partial line.
5.2.4.4. arrayOut

Writes the data in array to the stream. If LINES is specified, each element of the array is written using lineout(). If CHARS is specified, each element is written using charout(). The default method is LINES.

5.2.4.5. charIn

Returns a string of up to length characters from the input stream. The stream advances advances the read pointer by the number of characters read. If you omit length, it defaults to 1. If you specify start, this positions the read pointer before reading. The start value must be a positive whole number within the bounds of the stream. If the value is not a positive whole number, a syntax condition is raised. When the value is past the end of the stream, the empty string is returned and the NOTREADY condition is raised. If the stream is not already open, the stream attempts to open for reading and writing. If that fails, the stream opens for input only.

5.2.4.6. charOut

Returns the count of characters remaining after trying to write string to the output stream. The stream also advances the write pointer.

The string can be the null string. In this case, charOut writes no characters to the stream and returns 0. If you omit string, charOut writes no characters to the stream and returns 0. The stream is also closed.

If you specify start, this positions the write pointer before writing. If the stream is not already open, the stream attempts to open for reading and writing. If that fails, the stream opens for output only.

5.2.4.7. chars

Returns the total number of characters remaining in the input stream. The count includes any line separator characters, if these are defined for the stream. For persistent the count is the count of characters from the current read position. (See Input and Output Streams for a discussion of Rexx input and output.) The total number of characters remaining cannot be determined for some streams (for example, STDIN).
Chapter 5. The Builtin Classes

For these streams, the CHARS method returns 1 to indicate that data is present, or 0 if no data is present. For Windows devices, CHARS always returns 1.

5.2.4.8. close

```>>-close-------------------------------->_<
```

Closes the stream. close returns READY: if closing the stream is successful, or an appropriate error message. If you have tried to close an unopened file, then the close method returns a null string ("").

5.2.4.9. command

```>>-command(stream_command)-------------------------------->_<
```

Returns a string after performing the specified stream_command. The returned string depends on the stream_command performed and can be the null string. The following stream_commands:

- Open a stream for reading, writing, or both
- Close a stream at the end of an operation
- Move the line read or write position within a persistent stream (for example, a file)
- Get information about a stream

If the method is unsuccessful, it returns an error message string in the same form that the description method uses.

For most error conditions, the additional information is in the form of a numeric return code. This return code is the value of ERRNO that is set whenever one of the file system primitives returns with a -1.

5.2.4.9.1. Command Strings

The argument stream_command can be any expression that to one of the following command strings:

```+-BOTH|-- Write Options |-
```

```+-OPEN-------------------------+--+-------------+-+
 |  +-READ--------------------+ +-| Options |-+ |
 |  +-WRITE----------------++-| |
 |  +-APPEND++ |
 |  +-REPLACE--+
 ```

```+-CLOSE----------------------------------------------+
```

```+-FLUSH----------------------------------------------+
```

```+-SEEK-----+--+-----+-offset--+-------+--+------+--+
 |  +-POSITION+ +- < -+ +-READ--+ +-LINE-- |
 |  +- + +- |
 |  +- - -+ |
 ```

```+-QUERY++DATETIME--------------------------+-------+
```

```+-EXISTS----------------------------+
```

```+-HANDLE----------------------------+
```

```| +-CHAR+- |
```
Chapter 5. The Builtin Classes

Write Options:

+-SEEK----+-READ---------+-+
| +-POSITION-+  | +-LINE-+  |
|  | +-CHAR-+  |
|  | +-WRITE-+-+
|  | +-LINE-+  |
|  | +-SYS------+
+-SIZE----------------------------------------+
+-STREAMTYPE------------------------+
+-TIMESTAMP-------------------------+

Write Options:

|--+-APPEND--+
+-REPLACE++

Options:

+--------------------------------+-
| V |
+--------------------------------+-
+-SHARED--+-BINARY-----+-
+-SHAREREAD+-RECLENGTH--length+-
+-SHAREWRITE+

OPEN

Opens the stream object and returns READY=. (If unsuccessful, the previous information about return codes applies.) The default for OPEN is to open the stream for both reading and writing data, for example: 'OPEN BOTH'. To specify that the stream be only opened for input or output, add READ or WRITE, to the command string.

The following is a description of the options for OPEN:

READ

Opens the stream only for reading.

WRITE

Opens the stream only for writing.

BOTH

Opens the stream for both reading and writing. (This is the default.) The stream maintains separate read and write pointers.

APPEND

Positions the write pointer at the end of the stream. The write pointer cannot be moved anywhere within the extent of the file as it existed when the file was opened.
Chapter 5. The Builtin Classes

REPLACE

Sets the write pointer to the beginning of the stream and truncates the file. In other words, this option deletes all data that was in the stream when opened.

SHARED

Enables another process to work with the stream in a shared mode. This mode must be compatible with the shared mode (SHARED, SHAREREAD, or SHAREWRITE) used by the process that opened the stream.

SHAREREAD

Enables another process to read the stream in a shared mode.

SHAREWRITE

Enables another process to write the stream in a shared mode.

NOBUFFER

Turns off buffering of the stream. All data written to the stream is flushed immediately to the operating system for writing. This option can have a severe impact on output performance. Use it only when data integrity is a concern, or to force interleaved output to a stream to appear in the exact order in which it was written.

BINARY

Opens the stream in binary mode. This means that line end characters are ignored; they are treated like any other byte of data. This is intended to process binary data using the line operations.

Note: Specifying the BINARY option for a stream that does not exist but is opened for writing also requires the RECLENGTH option to be specified. Omitting the RECLENGTH option in this case raises an error condition.

RECLENGTH length

Allows the specification of an exact length for each line in a stream. This allows line operations on binary-mode streams to operate on individual fixed-length records. Without this option, line operations on binary-mode files operate on the entire file (for example, as if you specified the RECLENGTH option with a length equal to that of the file). The length must be 1 or greater.

Examples:

stream_name~command("open")
stream_name~command("open write")
stream_name~command("open read")
stream_name~command("open read shared")
Chapter 5. The Builtin Classes

CLOSE

Closes the stream object. The COMMAND method with the CLOSE option returns READY: if the stream is successfully closed or an appropriate error message otherwise. If an attempt to close an unopened file occurs, then the COMMAND method with the CLOSE option returns a null string (""").

FLUSH

Forces any data currently buffered for writing to be written to this stream.

SEEK offset

Sets the read or write position to a given number (offset) within a persistent stream. If the stream is open for both reading and writing and you do not specify READ or WRITE, both the read and write positions are set.

Note: See Input and Output Streams for a discussion of read and write positions in a persistent stream.

To use this command, you must first open the stream (with the OPEN stream command described previously or implicitly with an input or output operation). One of the following characters can precede the offset number.

= explicitly specifies the offset from the beginning of the stream. This is the default if you supply no prefix. For example, an offset of 1 with the LINE option means the beginning of the stream.

< specifies offset from the end of the stream.

+ specifies offset forward from the current read or write position.

- specifies offset backward from the current read or write position.

The command method with the SEEK option returns the new position in the stream if the read or write position is successfully located, or an appropriate error message.

The following is a description of the options for SEEK:

READ

specifies that this command sets the read position.

WRITE

specifies that this command sets the write position.
Chapter 5. The Builtin Classes

CHAR

specifies the positioning in terms of characters. This is the default.

LINE

specifies the positioning in terms of lines. For non-binary streams, this is potentially an operation that can take a long time to complete because, in most cases, the file must be scanned from the top to count the line-end characters. However, for binary streams with a specified record length, the new resulting line number is simply multiplied by the record length before character positioning. See Line versus Character Positioning for a detailed discussion of this issue.

Note: If you do line positioning in a file open only for writing, you receive an error message.

Examples:

stream_name~command("seek =2 read")
stream_name~command("seek +15 read")
stream_name~command("seek -7 write line")
fromend = 125
stream_name~command("seek <"fromend read")

POSITION

is a synonym for SEEK.

Used with these stream_commands, the COMMAND method returns specific information about a stream. Except for QUERY HANDLE and QUERY POSITION, the stream returns the query information even if the stream is not open. The stream returns the null string for nonexistent streams.

QUERY DATETIME

Returns the date and time stamps of a stream in US format. For example:

stream_name~command("query datetime")

A sample output might be:

11-12-95 03:29:12

QUERY EXISTS

Returns the full path specification of the stream object, if it exists, or a null string. For example:

stream_name~command("query exists")

A sample output might be:

c:\data\file.txt

QUERY HANDLE

Returns the handle associated with the open stream. For example:

stream_name~command("query handle")
Chapter 5. The Builtin Classes

A sample output might be: 3

QUERY POSITION

Returns the current read or write position for the stream, as qualified by the following options:

READ

Returns the current read position.

WRITE

Returns the current write position.

Note: If the stream is open for both reading and writing, this returns the read position by default. Otherwise, this returns the appropriate position by default.

CHAR

Returns the position in terms of characters. This is the default.

LINE

Returns the position in terms of lines. For non-binary streams, this operation can take a long time to complete. This is because the language processor starts tracking the current line number if not already doing so, and, thus, might require a scan of the stream from the top to count the line-end characters. See Line versus Character Positioning for a detailed discussion of this issue. For example:

   stream_name~command("query position write")

A sample output might be:

247

SYS

Returns the operating system stream position in terms of characters.

QUERY SEEK

Is a synonym for QUERY POSITION.

QUERY SIZE

Returns the size, in bytes, of a persistent stream. For example:

   stream_name~command("query size")

A sample output might be:

1305

QUERY STREAMTYPE

Returns a string indicating whether the stream is PERSISTENT, TRANSIENT, or UNKNOWN.
Chapter 5. The Builtin Classes

QUERY TIMESTAMP

Returns the date and time stamps of a persistent stream in an international format. This is the
preferred method of getting date and time because it provides the full 4-digit year. For example:

\[
\text{stream_name~command("query timestamp")}
\]

A sample output might be:

1995-11-12 03:29:12

5.2.4.10. description

\?><-description-------------------------------------------------><

Returns any descriptive string associated with the current state of the stream or the Nil object if no
descriptive string is available. The description method is identical with the STATE method except that
the string that description returns is followed by a colon and, if available, additional information about
ERROR or NOTREADY states.

5.2.4.11. flush

\?><-flush-------------------------------------------------------><

Returns READY:. It forces the stream to write any buffered data to the output stream.

5.2.4.12. init

\?><-init(name)-----------------------------------------------><

Initializes a stream object defined by name.

5.2.4.13. lineIn

\?><-lineIn-+-------------------------+--------------------------><

+-(+------------+)++
 +line-+ +-,count-+

Returns the next count lines. The count must be 0 or 1. The stream advances the read pointer. If you omit
count, it defaults to 1. A line number may be given to set the read position to the start of a specified line.
This line number must be positive and within the bounds of the stream, and must not be specified for a
transient stream. A value of 1 for line refers to the first line in the stream. If the stream is not already
open, the it tries to open the stream for reading and writing. If that fails, the stream is opened for input
only.
5.2.4.14. lineOut

```
>>-lineOut-+--------------------------+------------------------><
  +(-+--------+-+-------+-)-+
  +string+- +-,line+-
```

Returns 0 if successful in writing string to the output stream or 1 if an error occurs while writing the line. The stream advances the write pointer. If you omit string, the stream is closed. If you specify line, this positions the write pointer before writing. If the stream is not already open, the stream attempts to open for reading and writing. If that fails, the stream is opened for output only.

5.2.4.15. lines

```
+-Count--+--------------------------------------><
>>-lines(--+--------+---)--------------------------------------><
  +-Normal+-
```

Returns the number of completed lines that available for input. If the stream has already been read with charIn emphasis, this can include an initial partial line. For persistent streams the count starts at the current read position. In effect, lines reports whether a read action of charIn (see charIn) or lineIn (see lineIn) will succeed. (For an explanation of input and output, see Input and Output Streams.)

For a Queue, lines returns the actual number of lines.

**Note:** The chars method returns the number of characters in a persistent stream or the presence of data in a transient stream. The lines emphasis method determines the actual number of lines by scanning the stream starting at the current position and counting the lines. For large streams, this can be a time-consuming operation. Therefore, avoid the use of the LINES method in the condition of a loop reading a stream. It is recommended that you use the chars method.

The ANSI Standard has extended this function to allow an option: "Count". If this option is used, lines returns the actual number of complete lines remaining in the stream, irrespective of how long this operation takes.

The option "Normal" returns 1 if there is at least one complete line remaining in the file or 0 if no lines remain.

The default is "Count".

5.2.4.16. makeArray

```
+-{LINES}-+
>>-makeArray--+---------------------------------------><
  +-{CHARS}-+
```

Returns a fixed array that contains the data of the stream in line or character format, starting from the current read position. The line format is the default.

If you have used the charIn method, the first line can be a partial line.
5.2.4.17. open

Opens the stream and returns READY. If the method is unsuccessful, it returns an error message string in the same form that the description method uses.

For most error conditions, the additional information is in the form of a numeric return code. This return code is the value of ERRNO, which is set whenever one of the file system primitives returns with a -1.

By default, open opens the stream for both reading and writing data, for example: 'open BOTH'. To specify that the stream be only opened for input or output, specify READ or WRITE.

The options for the open method are:

READ
   Opens the stream for input only.

WRITE
   Opens the stream for output only.

BOTH
   Opens the stream for both input and output. (This is the default.) The stream maintains separate read and write pointers.

APPEND
   Positions the write pointer at the end of the stream. (This is the default.) The write pointer cannot be moved anywhere within the extent of the file as it existed when the file was opened.

REPLACE
   Sets the write pointer to the beginning of the stream and truncates the file. In other words, this option deletes all data that was in the stream when opened.
Chapter 5. The Builtin Classes

SHARED
Enables another process to work with the stream in a shared mode. (This is the default.) This mode must be compatible with the shared mode (SHARED, SHAREREAD, or SHAREWRITE) used by the process that opened the stream.

SHAREREAD
Enables another process to read the stream in a shared mode.

SHAREWRITE
Enables another process to write the stream in a shared mode.

NOBUFFER
Turns off buffering of the stream. All data written to the stream is flushed immediately to the operating system for writing. This option can have a severe impact on output performance. Use it only when data integrity is a concern, or to force interleaved output to a stream to appear in the exact order in which it was written.

BINAR
Opens the stream in binary mode. This means that line-end characters are ignored; they are treated like any other byte of data. This is for processing binary record data using the line operations.

Note: Specifying the BINARY option for a stream that does not exist but is opened for writing also requires the RECLENGTH option to be specified. Omitting the RECLENGTH option in this case raises an error condition.

RECLENGTH length
Allows the specification of an exact length for each line in a stream. This allows line operations on binary-mode streams to operate on individual fixed-length records. Without this option, line operations on binary-mode files operate on the entire file (for example, as if you specified the RECLENGTH option with a length equal to that of the file). The length must be 1 or greater.

Examples:

stream_name=open
stream_name=open("write")
stream_name=open("read")

5.2.4.18. position

+- = ++ +--CHAR++
>>-position(++++---offset--+READ--+---------+)-------------><
   +- < ++ +--WRITE++ +--LINE++
   +- + ++
   +- - ++
position is a synonym for seek. (See seek.)

5.2.4.19. qualify

>>>-qualify--------------------------------------------------------------------------><

Returns the stream’s fully qualified name. The stream need not be open.

5.2.4.20. query

>>>-query(-----DATETIME----------------------------------------------)<

+EXISTS+-+-+-+-+-+-+-
+HANDLE+-+
| +CHAR-+-
| +++SEEK-----+-+READ--+-
| ++POSITION+-+ +LINE-+-
| | +CHAR-+-
| | +WRITE---+-+
| | +LINE-+-
| | +SYS--+
| +SIZE+-
+-STREAMTYPE------------------
+-TIMESTAMP-----------------

Used with these options, the query method returns specific information about a stream. Except for query HANDLE and query POSITION, the stream returns the query information even if the stream is not open. A null string is returned for nonexistent streams.

DATETIME

returns the date and time stamps of a persistent stream in US format. For example:

```
stream_name~query("datetime")
```

A sample output might be:

```
11-12-98  03:29:12
```

EXISTS

returns the full path specification of the stream, if it exists, or a null string. For example:

```
stream_name~query("exists")
```

A sample output might be:

```
c:\data\file.txt
```

HANDLE

returns the handle associated with the open stream. For example:

```
stream_name~query("handle")
```

A sample output might be:
Chapter 5. The Builtin Classes

POSITION
returns the current read or write position for the stream, as qualified by the following options:

READ
returns the current read position.

WRITE
returns the current write position.

Note: If the stream is open for both reading and writing, this returns the read position by default. Otherwise, this returns the specified position.

CHAR
returns the position in terms of characters. This is the default.

LINE
returns the position in terms of lines. For non-binary streams, this operation can take a long time to complete. This is because the language processor starts tracking the current line number if not already doing so, and, thus, might require a scan of the stream from the top to count the line-end characters. See Line versus Character Positioning for a detailed discussion of this issue. For example:

\texttt{stream_name}^\texttt{query}(\texttt{"position write"})

A sample output might be:

247

SYS
returns the operating system stream position in terms of characters.

SIZE
returns the size, in bytes, of a persistent stream. For example:

\texttt{stream_name}^\texttt{query}(\texttt{"size"})

A sample output might be:

1305

STREAMTYPE
returns a string indicating whether the stream object is PERSISTENT, TRANSIENT, or UNKNOWN.
Chapter 5. The Builtin Classes

TIMESTAMP

returns the date and time stamps of a persistent stream in an international format. This is the preferred method of getting the date and time because it provides the full 4-digit year. For example:

```plaintext
stream_name~query("timestamp")
```

A sample output might be:

1998-11-12 03:29:12

5.2.4.21. say

```plaintext
>>-say--+-string-->

+-(-+-+++)++

+-string--+
```

Returns 0 if successful in writing `string` to the output stream or 1 if an error occurs while writing the line.

5.2.4.22. seek

```plaintext
>>-seek(-+-----+-offset-+-------+-+------+-)------------------->

+- < -+ +-READ+- +-LINE+-

+- + -+ +-WRITE+-

+- - -+
```

Sets the read or write position to a given number (offset) within a persistent stream. If the stream is open for both reading and writing and you do not specify READ or WRITE, both the read and write positions are set.

**Note:** See Input and Output Streams for a discussion of read and write positions in a persistent stream.

To use this method, you must first open the stream object (with the OPEN method described previously or implicitly with an input or output operation). One of the following characters can precede the offset number:

```
=
```

Explicitly specifies the offset from the beginning of the stream. This is the default if you supply no prefix. For example, an offset of 1 means the beginning of the stream.

```
<
```

Specifies offset from the end of the stream.

```
+
```

Specifies offset forward from the current read or write position.
Chapter 5. The Builtin Classes

- Specifies offset backward from the current read or write position.

The seek method returns the new position in the stream if the read or write position is successfully located, or an appropriate error message.

The following is a description of the options for seek:

READ
    specifies that the read position be set.

WRITE
    specifies that the write position be set.

CHAR
    specifies that positioning be done in terms of characters. This is the default.

LINE
    specifies that the positioning be done in terms of lines. For non-binary streams, this is potentially an operation that can take a long time to complete because, in most cases, the file must be scanned from the top to count the line-end characters. However, for binary streams with a specified record length, the new resulting line number is simply multiplied by the record length before character positioning. See Line versus Character Positioning for a detailed discussion of this issue.

    **Note:** If you do line positioning in a file open only for writing, you receive an error message.

Examples:

stream_name.seek("="2 read")
stream_name.seek("+15 read")
stream_name.seek("-7 write line")
fromend = 125
stream_name.seek("<"fromend read)

5.2.4.23. state

>>>-state--------------------------<<<

Returns a string indicating the current stream state.

The returned strings are as follows:
Chapter 5. The Built-in Classes

ERROR
The stream has been subject to an erroneous operation (possibly during input, output, or through the STREAM function). See Errors during Input and Output. You might be able to obtain additional information about the error with the description method or by calling the STREAM function with a request for the description.

NOTREADY
The stream is known to be in such a state that the usual input or output operations attempted upon would raise the NOTREADY condition. (See Errors during Input and Output.) For example, a simple input stream can have a defined length. An attempt to read that stream (with CHARIN or LINEIN, perhaps) beyond that limit can make the stream unavailable until the stream has been closed (for example, with LINEOUT(name)) and then reopened.

READY
The stream is known to be in such a state that the usual input or output operations might be attempted. This is the usual state for a stream, although it does not guarantee that any particular operation will succeed.

UNKNOWN
The state of the stream is unknown. This generally means that the stream is closed or has not yet been opened.

5.2.4.24. string

>>>-string------------------------------------------------------><

Returns a string that indicates the name of the object the stream represents i.e. the name of the file.

5.2.4.25. supplier

>>>-supplier------------------------------------------------------><

Returns a StreamSupplier object for the stream containing the remaining stream lines and linenumber positions for the stream.

5.2.4.26. uninit

>>>-uninit------------------------------------------------------><

This method cleans up the object when it is garbage collected. It should not be invoked directly except via an uninit method of a subclass of the Stream class.

If the Stream class is subclassed and the subclass provides an uninit method then that method must invoke the superclass uninit method. For example:

::class CustomStream subclass Stream
5.3. The Collection Classes

A collection is an object that contains a number of items, which can be any objects. Every item stored in a Rexx collection has an associated index that you can use to retrieve the item from the collection with the AT or [] methods.

Each collection defines its own acceptable index types. Rexx provides the following collection classes:

Array
A sequenced collection of objects ordered by whole-number indexes.

Bag
A collection where the index and the item are the same object. Bag indexes can be any object and each index can appear more than once.

CircularQueue
The CircularQueue class allows for storing objects in a circular queue of a predefined size. Once the end of the queue has been reached, new item objects are inserted from the beginning, replacing earlier entries. The collected objects can be processed in FIFO (first in, first out) or in a stack-like LIFO (last in, first out) order.

Directory
A collection with character string indexes. Index comparisons are performed using the string == comparison method.

List
A sequenced collection that lets you add new items at any position in the sequence. A list generates and returns an index value for each item placed in the list. The returned index remains valid until the item is removed from the list.

Properties
A collection with character string indexes and values. Properties collections include support for saving and loading from disk files.
Chapter 5. The Builtin Classes

Queue

A sequenced collection with the items ordered as a queue. You can remove items from the head of the queue and add items at either its tail or its head. Queues index the items with whole-number indexes, in the order in which the items would be removed. The current head of the queue has index 1, the item after the head item has index 2, up to the number of items in the queue.

Relation

A collection with indexes that can be any object. A relation can contain duplicate indexes.

Set

A collection where the index and the item are the same object. Set indexes can be any object and each index is unique.

Stem

A collection with character string indexes constructed from one or more string segments. Index comparisons are performed using the string == comparison method.

Table

A collection with indexes that can be any object. A table contains no duplicate indexes.

IdentityTable

A collection with indexes that can be any object. The IdentityTable class determines index item matches by using an object identity comparison. With object identity matches, an index will only match the same object instance. An identity table contains no duplicate indexes.

5.3.1. Organization of the Collection Classes

The following shows the logical organization of the Collection Classes. This does NOT represent the order that methods are inherited but rather the organization of the classes.

Collection
MapCollection
Directory
Properties
Relation
Stem
Table
IdentityTable
OrderedCollection
Array
List
Queue
CircularQueue
SetCollection
Bag
Set
5.3.2. The Collection Class

The Collection class is a MIXIN class that defines the basic set of methods implemented by all Collections. Many of the Collection class methods are abstract and must be implemented by the inheriting subclasses.

Figure 5-12. The Collection Class

<table>
<thead>
<tr>
<th>Object</th>

</tr>
</tbody>
</table>

5.3.2.1. []

Returns the item associated with the specified index or indexes. If the collection has no item associated with the specified index or indexes, this method returns the Nil object. This is an abstract method that must be implemented by a subclasses.

5.3.2.2. []=

Add an item to the collection at the specified index. This is an abstract method that must be implemented by a subclasses.
5.3.2.3. allIndexes

>>> allIndexes--------------------------------------------------><

Return an array of all indexes used by this collection. This is an abstract method that must be implemented by a subclasses.

5.3.2.4. allItems

>>> allItems----------------------------------------------------><

Return an array containing all items stored in the collection. This is an abstract method that must be implemented by a subclasses.

5.3.2.5. at

+-+-------+
| V     |

>>> at(--index+-)---------------------------------------------><

Returns the item associated with the specified index or indexes. If the collection has no item associated with the specified index or indexes, this method returns the Nil object. This is an abstract method that must be implemented by a subclasses.

5.3.2.6. difference

>>> difference(argument)----------------------------------------><

Returns a new collection (of the same class as the receiver) containing only those items from the receiver whose indexes the argument collection does not contain. The argument can be any collection class object. The argument must also allow all of the index values in the receiver collection.

5.3.2.7. hasIndex

+-+-------+
| V     |

>>> hasIndex(--index+-)---------------------------------------><

Returns 1 (true) if the array contains an item associated with the specified index or indexes. Returns 0 (false) otherwise.

5.3.2.8. hasItem

>>> hasItem(item)-----------------------------------------------><
Chapter 5. The Builtin Classes

Returns 1 (true) if the collection contains the specified item at any index location. Returns 0 (false) otherwise.

5.3.2.9. index

>>>-index(item)----------------------------------------------->

Return the index associated with item. If item occurs more than once in the collection, the returned index value is undetermined. This is an abstract method which must be implemented by a subclass of this class.

5.3.2.10. intersection

>>>-intersection(argument)-------------------------------------->

Returns a new collection (of the same class as the receiver) containing only those items from the receiver whose indexes are in both the receiver collection and the argument collection. The argument can be any collection class object. The argument must also allow all of the index values in the receiver collection.

5.3.2.11. items

>>>-items-------------------------------------------------->

Returns the number of items in the collection.

5.3.2.12. makeArray

>>>-makeArray-------------------------------------------------->

Returns a single-index array with the same number of items as the receiver object. Any index with no associated item is omitted from the new array. Items in the new array will have the same order as the source array.

5.3.2.13. put

+--------+  
|        |
V       V
>>>-put(item---,index--)->

Add an item to the collection at the specified index. This is an abstract method that must be implemented by a subclass if this class.

5.3.2.14. subset

>>>-subset(argument)------------------------------------------>

Chapter 5. The Builtin Classes

Returns 1 (true) if all indexes in the receiver collection are also contained in the argument collection; returns 0 (false) otherwise. The argument can be any collection class object. The argument must also allow all of the index values in the receiver collection.

5.3.2.15. supplier

Returns a Supplier object for the collection. The supplier allows you to enumerate through the index/item pairs for the collection. The supplier is created from a snapshot of the collection and is unaffected by subsequent changes to the collection’s contents.

5.3.2.16. union

Returns a new collection of the same class as the receiver that contains all the items from the receiver collection and selected items from the argument collection. This method includes an item from argument in the new collection only if there is no item with the same associated index in the receiver collection and the method has not already included an item with the same index. The order in which this method selects items in argument is unspecified (the program should not rely on any order.). The argument can be any collection class object. The argument must also allow all of the index values in the receiver collection.

5.3.2.17. xor

Returns a new collection of the same class as the receiver that contains all items from the receiver collection and the argument collection; all indexes that appear in both collections are removed. The argument can be any collection class object. The argument must also allow all of the index values in the receiver collection.

5.3.3. The MapCollection Class

The MapCollection class is a MIXIN class that defines the basic set of methods implemented by all collections that use create a mapping from an index object to a value.
This class is defined as a mixin class.

### 5.3.3.1. Inherited Methods

Methods inherited from the Object class.

```plaintext
new (class method)  instanceMethod send
<= == \== <> >><
class                instanceMethods sendWith
isA                  isInstanceOf setMethod
setName              objectName start
hasMethod            objectName= string
identityHash         Request unsetMethod
init                  Run
```

Methods inherited from the Collection class.

```plaintext
[]                  hasIndex put
[]=                 hasItem subset
allIndexes          index supplier
allItems            intersection union
at                  items xor
difference          makeArray
```

### 5.3.3.2. putAll

```plaintext
>>>-putAll(collection)------------------------------------------><
```

Adds all items `collection` to the target directory. The `collection` argument can be any object that supports a supplier method. Items from `collection` are added using the index values returned by the supplier. The item indexes from the source `collection` must be strings. The items are added in the order provided by the supplier object. If duplicate indexes exist in `collection`, the last item provided by the supplier will overwrite previous items with the same index.

**5.3.3.3. makeArray**

Returns a single-index array of the index values used by the receiver object. The index objects will not be ordered in any predictable order.

**5.3.4. The OrderedCollection Class**

The OrderedCollection class is a MIXIN class that defines the basic set of methods implemented by all collections that have an inherent index ordering, such as an array or a list.

![Figure 5-14. The OrderedCollection class](image)

This class is defined as a mixin class.

**5.3.4.1. append**

Append an item to the end of the collection ordering. This is an abstract method that must be implemented by a subclass if this class.

**5.3.4.2. appendAll**

Append all items in the given collection to the end of the collection ordering.
Chapter 5. The Builtin Classes

Appends all items in collection to the end of the target collection. The *collection* may be any object that implements an allItems() method.

5.3.4.3. difference

```>>-difference(argument)----------------------------------------><``

Returns a new collection (of the same class as the receiver) containing only those items from the receiver that are not also contained in the *argument* collection. The *argument* can be any collection class object.

5.3.4.4. intersection

```>>-intersection(argument)--------------------------------------><``

Returns a new collection (of the same class as the receiver) containing only those items from the receiver that are in both the receiver collection and the *argument* collection. The *argument* can be any collection class object.

5.3.4.5. subset

```>>-subset(argument)--------------------------------------------><``

Returns 1 (true) if all items in the receiver collection are also contained in the *argument* collection; returns 0 (false) otherwise. The *argument* can be any collection class object.

5.3.4.6. union

```>>-union(argument)---------------------------------------------><``

Returns a new collection of the same class as the receiver that contains all the items from the receiver collection and selected items from the *argument* collection. This method includes an item from *argument* in the new collection only if there is no equivalent item in the receiver collection and the method has not already included. The order in which this method selects items in *argument* is unspecified (the program should not rely on any order.). The *argument* can be any collection class object.

5.3.4.7. xor

```>>-xor(argument)-----------------------------------------------><``

Returns a new collection of the same class as the receiver that contains all items from the receiver collection and the *argument* collection; all items that appear in both collections are removed. The *argument* can be any collection class object.
5.3.5. The SetCollection Class

This is a tagging mixin class only and does not define any methods of its own. Collections that implement SetCollection are MapCollections that constrain the index and item to be the same object.

Figure 5-15. The SetCollection class

This class is defined as a mixin class.

5.3.5.1. Inherited Methods

Methods inherited from the Object class.

new (class method) instanceMethod send
= \== \== << >> class instanceMethods sendWith
class isa setMethod
copy instanceOf start
defaultName objectName string
hasMethod objectName= startWith
identityHash Request unsetMethod
init Run

Methods inherited from the Collection class.

[] hasIndex put
[]= hasItem subset
allIndexes index supplier
allItems intersection union
at items xor
difference makeArray

5.3.6. The Array Class

An array is a possibly sparse collection with indexes that are positive whole numbers. You can reference array items by using one or more indexes. The number of indexes is the same as the number of
dimensions of the array. This number is called the dimensionality of the array.

Array items can be any valid Rexx object. If an object has not been assigned to an array index then that index is considered to contain the NIL object.

Figure 5-16. The Array class and methods

<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
</tr>
<tr>
<td>+ OrderedCollection</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>new of</th>
</tr>
</thead>
<tbody>
<tr>
<td>allIndexes</td>
</tr>
<tr>
<td>allItems</td>
</tr>
<tr>
<td>append</td>
</tr>
<tr>
<td>at, []</td>
</tr>
<tr>
<td>dimension</td>
</tr>
<tr>
<td>empty</td>
</tr>
<tr>
<td>first</td>
</tr>
<tr>
<td>hasIndex</td>
</tr>
<tr>
<td>hasItem</td>
</tr>
<tr>
<td>index</td>
</tr>
<tr>
<td>isEmpty</td>
</tr>
<tr>
<td>items</td>
</tr>
<tr>
<td>last</td>
</tr>
<tr>
<td>makeArray</td>
</tr>
</tbody>
</table>

Note: The Array class also has available class methods that its metaclass, the Class class, defines. It also inherits methods from the Ordered Collection class.

Array objects are variable-sized. The dimensionality of an array is fixed, but the size of each dimension is variable. When you create an array, you can specify a hint about how many elements you expect to put into the array or the array’s dimensionality. However, you do not need to specify a size or dimensionality of an array when you are creating it. You can use any whole-number indexes to reference items in an array.

For any array method that takes an index, the index may be specified as either individual arguments or as an array of indexes. For example, the following are equivalent:
Chapter 5. The Builtin Classes

```
x = myarray[1,2,3]  -- retrieves an item from a multi-dimension array
index = .array~of(1,2,3) -- create an index list
x = myarray[index]  -- also retrieves from "1,2,3"
```

Methods such as `index()` that return index items will return a single numeric value for single-dimension arrays and an array of indexes for multi-dimension arrays.

### 5.3.6.1. Inherited Methods

Methods inherited from the `Object` class.

- `new (class method) instanceMethod send`
- `== !== <= >= < > instanceMethods sendWith`
- `class isA setMethod`
- `copy isInstanceOf start`
- `defaultName objectName startWith`
- `hasMethod objectName= string`
- `identityHash Request unsetMethod`
- `init Run`

Methods inherited from the `Collection` class.

- `[] hasIndex put`
- `[]= hasItem subset`
- `allIndexes index supplier`
- `allItems intersection union`
- `at items xor`
- `difference makeArray`

Methods inherited from the `OrderedCollection` class.

- `append intersection xor`
- `appendAll subset`
- `difference union`

### 5.3.6.2. new (Class Method)

```
++-new-+------------------------------------------------------------------><
  | ++,------ | |
  | < V | |
  +-(----size-+-)--+
```

Returns a new empty array. If you specify any `size` arguments, the size is taken as a hint about how big each dimension should be. The Array classes uses this only to allocate the initial array object. For multiple dimension arrays, you can also specify how much space is to be allocated initially for each dimension of the array.

Each `size` argument must a non-negative whole number. If it is 0, the corresponding dimension is initially empty.

**Examples:**

```
a = .array~new()  -- create an new, empty array
```
5.3.6.3. \texttt{of (Class Method)}

\[
\begin{array}{c|c|c|c}
\texttt{+-,-----+} & \texttt{\texttt{+},----+} & \texttt{|} & \texttt{|} \\
\texttt{|} & \texttt{\texttt{V}} & \texttt{|} & \texttt{|} \\
\texttt{+-(-item-++--)++} & & & \\
\end{array}
\]

Returns a newly created single-index array containing the specified \textit{item} objects. The first \textit{item} has index 1, the second has index 2, and so on.

If you use the OF method and omit any argument items, the returned array does not include the indexes corresponding to those you omitted.

\textbf{Examples:}

\begin{verbatim}
a = .array\texttt{of("Fred", "Mike", "David")}

d o n a m e o v e r a
    s a y n a m e -- d i s p l a y s "Fred", "Mike", a n d "David"
end
\end{verbatim}

5.3.6.4. \texttt{[]}

\[
\begin{array}{c|c|c|c}
\texttt{+-,-----+} & \texttt{\texttt{+},----+} & \texttt{|} & \texttt{|} \\
\texttt{|} & \texttt{\texttt{V}} & \texttt{|} & \texttt{|} \\
\texttt{+-[-index++]---------------------------><} & & & \\
\end{array}
\]

Returns the same value as the \texttt{at()} method.

Note that the \textit{index} argument may also be specified as an array of indexes.

5.3.6.5. \texttt{[]=}

\[
\begin{array}{c|c|c|c}
\texttt{+-,-----+} & \texttt{\texttt{+},----+} & \texttt{|} & \texttt{|} \\
\texttt{|} & \texttt{\texttt{V}} & \texttt{|} & \texttt{|} \\
\texttt{+-[-index++]=value---------------------------><} & & & \\
\end{array}
\]

This method is the same as the \texttt{put()} method.

Note that the \textit{index} argument may also be specified as an array of indexes.

5.3.6.6. \texttt{allIndexes}

\[
\begin{array}{c|c|c|c}
\texttt{+-allIndexes---------------------------><} & & & \\
\end{array}
\]

Returns an array of all index positions in the array containing items. For multi-dimension arrays, each returned index will be an array of index values.

\textbf{Examples:}

\begin{verbatim}
a = .array\texttt{of("Fred", "Mike", "David")}
\end{verbatim}
Chapter 5. The Builtin Classes

do name over a~allIndexes
    say name -- displays "1", "2", and "3"
end

a~remove(2) -- remove second item

do name over a~allIndexes
    say name -- displays "1" and "3"
end

5.3.6.7. allItems

>>-allItems----------------------------------------------------><

Returns an array of all items contained in the array.

Examples:

a = .array~of("Fred", "Mike", "David")

do name over a~allItems
    say name -- displays "Fred", "Mike", and "David"
end

a~remove(2) -- remove second item

do name over a~allItems
    say name -- displays "Fred" and "David"
end

5.3.6.8. append

>>-append(item)------------------------------------------------><

Appends an item to the array after the last item (the item with the highest index). The return value is the index of newly added item.

Examples:

a = .array~of("Mike", "Rick")
a~append("Fred") -- a = .array~of("Mike", "Rick", "Fred")

5.3.6.9. at

+++-,-----+
    V     |
>>-at(--index--++)--------------------------------------------><
Returns the item associated with the specified index or indexes. If the array has no item associated with the specified index or indexes, this method returns the Nil object.

Note that the index argument may also be specified as an array of indexes.

Examples:

```
a = .array~of("Mike", "Rick")
say a~at(2) -- says: "Rick"
```

### 5.3.6.10. dimension

```
>>>-dimension------------------------------------------><
+-n+-
```

Returns the current size (upper bound) of dimension \(n\) (a positive whole number). If you omit \(n\), this method returns the dimensionality (number of dimensions) of the array. If the number of dimensions has not been determined, 0 is returned.

Examples:

```
a = .array~of(,"Mike", "Rick")
say a~dimension -- says: 1 (number of dimensions in the array)
say a~dimension(1) -- says: 3 (upper bound of dimension one)

a = .array~new~~put("Mike",1,1)~~put("Rick",1,2)
say a~dimension -- says: 2 (number of dimensions in the array)
say a~dimension(1) -- says: 1 (upper bound of dimension one)
say a~dimension(2) -- says: 2 (upper bound of dimension two)
```

### 5.3.6.11. empty

```
>>>-empty------------------------------------------------------><
```

Removes all items from the array.

Examples:

```
a = .array~of("Mike", "Rick", "Fred", "Rick")
a~empty -- a = .array~new
```

### 5.3.6.12. first

```
>>>-first------------------------------------------------------><
```

Returns the index of the first item in the array or the Nil object if the array is empty. For multi-dimention arrays, the index is returned as an array of index values.

Examples:
Chapter 5. The Builtin Classes

```rexx
a = .array~of("Mike", "Rick", "Fred", "Rick")
say a.first -- says: 1
a = .array~of("Mike", "Rick")
say a.first -- says: 2
```

5.3.6.13. hasIndex

```
+-,------
 V   | |
>>-hasIndex(---index-+-)---------------------------------------><
```

Returns 1 (true) if the array contains an item associated with the specified index or indexes. Returns 0 (false) otherwise.

Note that the index argument may also be specified as an array of indexes.

Examples:

```rexx
a = .array~of("Mike", "Rick", "Fred", "Rick")
say a.hasIndex(2) -- says: 1
say a.hasIndex(5) -- says: 0
```

5.3.6.14. hasItem

```
>>-hasItem(item)-----------------------------------------------><
```

Returns 1 (true) if the array contains the specified item at any index location. Returns 0 (false) otherwise. Item equality is determined by using the == method of `item`.

Examples:

```rexx
a = .array~of("Mike", "Rick", "Fred", "Rick")
say a.hasItem("Rick") -- says: 1
say a.hasItem("Mark") -- says: 0
```

5.3.6.15. index

```
>>-index(item)-------------------------------------------------><
```

Returns the index of the specified item within the array. If the target item appears at more than one index, the first located index will be returned. For multi-dimension arrays, the index is returned as an array of index values. If the array does not contain the specified item, .nil is returned. Item equality is determined by using the == method of `item`.

Examples:

```rexx
a = .array~of("Mike", "Rick", "Fred", "Rick")
say a.index("Rick") -- says: 2
```
5.3.6.16. isEmpty

Returns 1 (true) if the array is empty. Returns 0 (false) otherwise.

Examples:
```rexx
a = .array~new
say a~isEmpty -- says: 1
a[1] = "i"
say a~isEmpty -- says: 0
```

5.3.6.17. items

Returns the number of items in the collection.

Examples:
```rexx
a = .array~of("Fred", , "Mike", , "David")
say a~items -- says: 3
```

5.3.6.18. last

Returns the index of the last item in the array or the Nil object if the array is empty. For multi-dimension arrays, index is returned as an array of index items.

Examples:
```rexx
a = .array~of("Fred", , "Mike", , "David")
say a~last -- says: 5
```

5.3.6.19. makeArray

Returns a single-index array with the same number of items as the receiver object. Any index with no associated item is omitted from the new array. Items in the new array will have the same order as the source array. Multi-dimension arrays arrays will be converted into a non-sparse single dimension array.

Examples:
```rexx
a = .array~of("Fred", , "Mike", , "David")
b = a~makeArray -- b = .array~of("Fred", "Mike", "David")
```
5.3.6.20. makeString

`+-,separator-+
+-(LINE)--+-
>>-makeString(+----------------+------------------++)------------><+
+-(CHAR)--+
+-(LINE)--+

Returns a string that contains the data of an array. The elements of the array are treated either in line or character format, starting at the first element in the array. The line format is the default. If the line format is use, a separator string can be specified. The separator will be used between concatenated elements instead of the default line end separator.

Examples:

See `toString` for examples.

5.3.6.21. next

`>>-next(index)--------------------------------------------><`

Returns the index of the item that follows the array item having index `index` or returns the Nil object if the item having that index is last in the array. For multi-dimension arrays, the same ordering used by the `allItems` method is used to determine the next position and the index is returned as an array of index values.

Note that the `index` argument may also be specified as an array of indexes.

Examples:

```rexx
a = .array~of("Fred", , "Mike", , "David")
say a~next(3) -- says: 5
```

5.3.6.22. previous

`>>-previous(index)--------------------------------------------><`

Returns the index of the item that precedes the array item having index `index` or the Nil object if the item having that index is first in the array. For multi-dimension arrays, the same ordering used by the `allItems` method is used to determine the previous position and the index is returned as an array of index values.

Note that the `index` argument may also be specified as an array of indexes.

Examples:

```rexx
a = .array~of("Fred", , "Mike", , "David")
say a~previous(3) -- says: 1
```

5.3.6.23. put

`+--------+
V |
`
Chapter 5. The Builtin Classes

>>-put(item---,index-+-)---------------------------------------><

Makes the object item a member item of the array and associates it with the specified index or indexes. This replaces any existing item associated with the specified index or indexes with the new item. If the index for a particular dimension is greater than the current size of that dimension, the array is expanded to the new dimension size.

Note that the index argument may also be specified as an array of indexes.

Examples:

a = .array~new
a~put("Fred", 1) -- a = .array~of("Fred")
a~put("Mike", 2) -- a = .array~of("Fred", "Mike")
a~put("Mike", 1) -- a = .array~of("Mike", "Mike")

do name over a
   say name
end

/* Output would be: */

Mike
Mike

5.3.6.24. remove

+-,------
|         v
>>-remove(---index-+-)---------------------------------------><

Returns and removes the member item with the specified index or indexes from the array. If there is no item with the specified index or indexes, the Nil object is returned and no item is removed.

Note that the index argument may also be specified as an array of indexes.

Examples:

a = .array~of("Fred", "Mike", "Mike", "David")
a~remove(2) -- removes "Mike"

5.3.6.25. removeItem

>>-removeItem(item)--------------------------------------------><

Removes an item from the array. If the target item exists at more than one index, the first located item is removed. Item equality is determined by using the == method of item. The return value is the removed item.

Examples:

a = .array~of("Fred", "Mike", "Mike", "David")
5.3.6.26. section

Returns a new array (of the same class as the receiver) containing selected items from the receiver array. The first item in the new array is the item corresponding to index $start$ in the receiver array. Subsequent items in the new array correspond to those in the receiver array (in the same sequence). If you specify the whole number $items$, the new array contains only this number of items (or the number of subsequent items in the receiver array, if this is less than $items$). If you do not specify $items$, the new array contains all subsequent items of the receiver array. The receiver array remains unchanged. The section() method is valid only for single-index arrays.

Note that the $start$ argument, (the $index$ argument,) may also be specified as an array of indexes.

Examples:

```rexx
a = .array~of(1,2,3,4) -- Loads the array
b = a~section(2) -- b = .array~of(2,3,4)
c = a~section(2,2) -- c = .array~of(2,3)
d = a~section(2,0) -- d = .array~new
```

5.3.6.27. size

Returns the number of items that can be placed in the array before it needs to be extended. This value is the same as the product of the sizes of the dimensions in the array.

5.3.6.28. sort

Sorts an array of Comparable items into ascending order using an unstable Quicksort algorithm. See Sorting Arrays for details.

5.3.6.29. sortWith

Sorts an array of items into ascending order using an unstable Quick sort algorithm. Ordering of elements is determined using the $comparator$ argument. See Sorting Arrays for details.
5.3.6.30. stableSort

>stableSort-------------------------------------------------->

Sorts an array of Comparable items into ascending order using a stable Mergesort algorithm. See Sorting Arrays for details.

5.3.6.31. stableSortWith

>stableSortWith(comparator)---------------------------------->

Sorts an array of items into ascending order using a stable Mergesort algorithm. Ordering of elements is determined using the comparator argument. See Sorting Arrays for details.

5.3.6.32. supplier

>supplier---------------------------------------------------->

Returns a Supplier object for the collection. The supplier allows you to iterate over the index/item pairs for the collection. The supplier enumerates the array items in their sequenced order. For multi-dimensional arrays, the supplier index method will return the index values as an array of index numbers.

Examples:

a = .array~of(“Fred”, “Mike”, “David”)
sup = a~supplier
a~append(“Joe”)
do while sup~available
    say sup~item -- displays “Fred”, “Mike”, and “David”
sup~next
end

5.3.6.33. toString

>toString(-+---------+--------------+-)---------------------->

Returns a string that contains the data of an array (one to n dimensional). The elements of the array are treated either in line or character format, starting at the first element in the array. The line format is the default. If the line format is use, a separator string can be specified. The separator will be used between concatenated elements instead of the default line end separator.

Examples:

a = .array~of(1,2,3,4) -- Loads the array
Chapter 5. The Builtin Classes

say a~toString -- Produces: 1
-- 2
-- 3
-- 4

say a~toString("c") -- Produces: 1234

say a~toString(,,") -- Produces: 1, 2, 3, 4

5.3.6.3.4. Examples

array1=.array~of(1,2,3,4) /* Loads the array */

/* Alternative way to create and load an array */
array2=.array~new(4) /* Creates array2, containing 4 items */
do i=1 to 4 /* Loads the array */
   array2[i]=i
end

You can produce the elements loaded into an array, for example:

do i=1 to 4
   say array1[i]
end

If you omit any argument values before arguments you supply, the corresponding indexes are skipped in the returned array:

directions=.array~of("North","South",,"West")
do i=1 to 4 /* Produces: North */
   say directions[i] /* South */
   /* The Nil object */
   /* West */
end

Here is an example using the ~~:

z=.array~of(1,2,3)~~put(4,4)
do i = 1 to z~size
   say z[i] /* Produces: 1 2 3 4 */
end

5.3.7. The Bag Class

A bag is a non-sparse collection that restricts the elements to having an item that is the same as the index. Any object can be placed in a bag, and the same object can be placed in a bag several times.
Figure 5-17. The Bag class and methods

```
<table>
<thead>
<tr>
<th>Bag</th>
</tr>
</thead>
<tbody>
<tr>
<td>+ SetCollection</td>
</tr>
<tr>
<td>of</td>
</tr>
<tr>
<td>difference</td>
</tr>
<tr>
<td>hasIndex</td>
</tr>
<tr>
<td>intersection</td>
</tr>
<tr>
<td>makeArray</td>
</tr>
<tr>
<td>put, []=</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>putAll</td>
</tr>
<tr>
<td>subset</td>
</tr>
<tr>
<td>union</td>
</tr>
<tr>
<td>xor</td>
</tr>
</tbody>
</table>
```

**Note:** The Bag class also has available class methods that its metaclass, the `Class` class, defines. It also inherits methods from the `Set Collection` class, although there are not currently any methods defined in that class.

The Bag class is a subclass of the Relation class. In addition to its own methods, it inherits the methods of the Object class and the Relation class.

### 5.3.7.1. Inherited Methods

Methods inherited from the `Object` class.

```
new (class method)  instanceMethod  send
<= <= \== <= <> ><  instanceMethods  sendWith
class               isA                start
copy                isInstanceOf       setMethod
defaultName         objectName         startWith
hasMethod           objectName=        string
identityHash        Request             unsetMethod
init                 Run
```

Methods inherited from the `Collection` class.
Chapter 5. The Builtin Classes

- hasIndex
- put
- []=
- hasItem
- subset
- allIndexes
- index
- supplier
- allItems
- intersection
- union
- at
- items
- xor
- difference
- makeArray

Methods inherited from the MapCollection class.

- putAll

Methods inherited from the Relation class.

- new (class method)
- empty
- put
- allAt
- hasIndex
- []=
- allItem
- hasItem
- remove
- allIndexes
- index
- removeItem
- allItems
- intersection
- subset
- at
- isEmpty
- supplier
- [ ]
- items
- union
- difference
- makeArray
- xor

5.3.7.2. of (Class Method)

```
  +-------+
  | V     |
  |       |
  | >>>-of(--item-->)----------------------------------------------><
```

Returns a newly created bag containing the specified item objects.

5.3.7.3. []=

```
  >>>-[index]=item------------------------------------------------><
```

Adds an item to the Bag. This method is the same as the put() method.

5.3.7.4. difference

```
  >>>-difference(argument)----------------------------------------><
```

Returns a new Bag containing only those items from the receiver that the argument collection does not contain. The argument can be any collection class object.

5.3.7.5. hasIndex

```
  >>>-hasIndex(index)---------------------------------------------><
```

Returns 1 (true) if the collection contains any item associated with index index, or 0 (false). Index equality is determined by using the == method of index.
5.3.7.6. intersection

\>
\>-intersection(argument)--------------------------------------><

Returns a new Bag containing only those items from the receiver that are in also in the argument collection. The argument can be any collection class object.

5.3.7.7. put

\>
\>-put(item,index)---------------------------------------------><

Makes the object item a member item of the bag and associates it with index index. If the relation already contains any items with index index, this method adds a new member item item with the same index, without removing any existing member items.

5.3.7.8. putAll

\>
\>-putAll(collection)------------------------------------------><

Adds all items collection to the target bag. The collection argument can be any object that supports a supplier method. Items from collection are added using the item values returned by the supplier.

5.3.7.9. subset

\>
\>-subset(argument)--------------------------------------------><

Returns 1 (true) if all indexes in the receiver collection are also contained in the argument collection; returns 0 (false) otherwise. The argument can be any collection class object.

5.3.7.10. union

\>
\>-union(argument)---------------------------------------------><

Returns a new Bag that contains all the items from the receiver collection and selected items from the argument collection. The order in which this method selects items in argument is unspecified. The argument can be any collection class object.

5.3.7.11. xor

\>
\>-xor(argument)-----------------------------------------------><

Returns a new Bag that contains all items from the receiver collection and the argument collection; items that appear in both collections are removed. The argument can be any collection class object.
5.3.7.12. Examples

/* Create a bag of fruit */
fruit = .bag~of("Apple", "Orange", "Apple", "Pear")
say fruit~items /* How many pieces? (4) */
say fruit~items("Apple") /* How many apples? (2) */
fruit~remove("Apple") /* Remove one of the apples. */
fruit~put("Banana")~put("Orange") /* Add a couple. */
say fruit~items /* How many pieces? (5) */

5.3.8. The CircularQueue Class

The CircularQueue class allows for storing objects in a circular queue of a predefined size. Once the end of the queue has been reached, new item objects are inserted from the beginning, replacing earlier entries. Any object can be placed in the queue and the same object can occupy more than one position in the queue.

The collected objects can be processed in FIFO (first in, first out) or in a stack-like LIFO (last in, first out) order.
5.3.8.1. Inherited Methods

Methods inherited from the Object class.

```
new (class method) instanceMethod send
== <= \>= <= <= > <= sendWith
class isA setMethod
copy isInstanceOf start
defaultName objectName startWith
hasMethod objectName= string
identityHash Request unsetMethod
init Run
```

Methods inherited from the Collection class.

```
[] hasIndex put
|= hasItem subset
allIndexes index supplier
allItems intersection union
at items xor
difference makeArray
```

Methods inherited from the OrderedCollection class.

```
append intersection xor
appendAll subset
difference union
```

Methods inherited from the Queue class.

```
new (class method) hasItem pull
of (class method) index push
allIndexes insert put
allItems isEmpty []= makeArray
append items queue
at last remove
[] makeArray removeItem
empty next supplier
first peek
hasIndex previous
```

5.3.8.2. of (Class Method)

```
>>-of+------------------------------------------------------------------------><
| +-,----+ |
| V | |
+-(--item---++)++
```

Returns a newly created circular queue containing the specified item objects. The first item has index 1, the second has index 2, and so on. The number of item objects determines the size of the circular queue.

5.3.8.3. init

```
>>-init------------------------------------------------------------------------><
```
Chapter 5. The Builtin Classes

Performs initialization of the circular queue.

5.3.8.4. makeArray

```
>>-makeArray(-+---------+-)------------------------------------><
    +--order--+
```

Returns a single-index array containing the items of the circular queue in the specified order.
The following order can be used. (Only the capitalized letter is needed; all characters following it are ignored.)

Fifo
   First-in, first-out order. This is the default.

Lifo
   Last-in, first-out order (stacklike).

5.3.8.5. push

```
>>-push(item-+------------+)-------------------------------------><
    +--,option---+
```

Makes the object item a member item of the circular queue, inserting the item object in front of the first item in the queue. The pushed item object will be the new first item in the circular queue.

If the circular queue is full, than the last item stored in the circular queue will be deleted, before the insertion takes place. In this case the deleted item will be returned, otherwise .nil.

If option is specified, it may be "Normal" or "Unique". The default is "Normal". Only the first letter of the option capitalized letter is required; all characters following it are ignored. If option is 'Unique', any matching item already in the queue will be removed before before item is added to the queue. removed before the operation is performed. This allows you to maintain a list like the recent files list of an editor.

5.3.8.6. queue

```
    +--,Normal---+
>>-queue(item-+------------+)----------------------------------><
    +--,Unique---+
```

Makes the object item a member item of the circular queue, inserting the item at the end of the circular queue.

If the circular queue is full, than the first item will be deleted, before the insertion takes place. In this case the deleted item will be returned, otherwise .nil.

If option is specified, it may be "Normal" or "Unique". The default is "Normal". Only the first letter of the option capitalized letter is required; all characters following it are ignored. If option is 'Unique', any
matching item already in the queue will be removed before before item is added to the queue. removed before the operation is performed. This allows you to maintain a list like the recent files list of an editor.

### 5.3.8.7. resize

```
>>-resize(-newSize-+----------+-)----------------------------------><
  +---,order--+
```

Resizes the circular queue object to be able to contain `newSize` items. If the previous size was larger than `newSize`, any extra items are removed in the specified `order`.

The following `order` can be used. (Only the capitalized letter is needed; all characters following it are ignored.)

**Fifo**

First-in, first-out. This keeps the most recently added items. This is the default action.

**Lifo**

Last-in, first-out (stacklike). This removes the most recently added items.

**Note:** Resizing with a value of 0 removes all items from the circular queue.

### 5.3.8.8. size

```
>>-size--------------------------------------------------------><
```

Returns the maximum number of objects that can be stored in the circular queue.

### 5.3.8.9. string

```
  +--","------+ +-,-Fifo--+

>>-string(-+-----------+--+---------+-)------------------------><

  +-delimiter-+ +-,-order-+
```

Returns a string object that concatenates the string values of the collected item objects, using the `delimiter` string to delimit them, in the specified `order`. The default `delimiter` is a single comma.

If the delimiter string argument is omitted the comma character (",") is used as the default delimiter string.

The following `order` can be used. (Only the capitalized letter is needed; all characters following it are ignored.)

**Fifo**

First-in, first-out. This is the default
Chapter 5. The Builtin Classes

Lifo
Last-in, first-out (stacklike)

5.3.8.10. supplier

```
>>-supplier(--------)------------------------------------><
   +--order---+
```

Returns a Supplier object for the collection. The supplier allows you to iterate over the items that were in the queue at the time of the supplier's creation.

The supplier will iterate over the items in the specified order. (Only the capitalized letter is needed; all characters following it are ignored.)

Fifo
First-in, first-out, default

Lifo
Last-in, first-out (stacklike)

5.3.8.11. Example

```rexx
-- create a circular buffer with five items
u=.circularQueue~of("a", "b", "c", "d", "e")
say "content: \["u\]\], "content (LIFO): \["u~string("->","L")\]"
say

u~resize(4, "FIFO")      -- resize fifo-style (keep newest)
say "after resizing to 4 items in FIFO style (keeping the newest):"
say "content: \["u\]\], "content (LIFO): \["u~string("->","L")\]"
say

u~resize(2, "LIFO")      -- resize lifo-style (keep oldest)
say "after resizing to 2 items in LIFO style (keeping the oldest):
say "content: \["u\]\], "content (LIFO): \["u~string("->","L")\]"
say

u~resize(0)              -- resize lifo-style (keep oldest)
say "after resizing to 0 items, thereby deleting all items:"
say "content: \["u\]\], "content (LIFO): \["u~string("->","L")\]"
say

u~resize(2)              -- resize lifo-style (keep oldest)
say "after resizing to 2, size="u~size "and items="u~items
say "after queuing the three items 'x', 'y', 'z':"
say "content: \["u\]\], "content (LIFO): \["u~string("->","L")\]"
say
```

236   ooRexx Reference Version 4.0.0
Chapter 5. The Builtin Classes

u~push('1')~push('2')~push('3')
say "after pushing the three items '1', '2', '3':"
say "content: ["u"], "content (LIFO): ["u~string("->","L")"]"
say

Output:

content: [a,b,c,d,e], content (LIFO): [e->d->c->b->a]

after resizing to 4 items in FIFO style (keeping the newest):
content: [b,c,d,e], content (LIFO): [e->d->c->b]

after resizing to 2 items in LIFO style (keeping the oldest):
content: [b,c], content (LIFO): [c->b]

after resizing to 0 items, thereby deleting all items:
content: [], content (LIFO): []

after resizing to 2, size=2 and items=0
after queuing the three items 'x', 'y', 'z':
content: [y,z], content (LIFO): [z->y]

after pushing the three items '1', '2', '3':
content: [3,2], content (LIFO): [2->3]

5.3.9. The Directory Class

A Directory is a MapCollection using unique character string indexes. The items of the collection can be any valid Rexx object.
Chapter 5. The Builtin Classes

Figure 5-19. The Directory class and methods

```
<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td>Directory</td>
</tr>
<tr>
<td>+ MapCollection</td>
</tr>
<tr>
<td>new</td>
</tr>
</tbody>
</table>

| allIndexes | items |
| allItems   | makeArray |
| at, []     | put, []= |
| empty      | remove |
| entry      | removeItem |
| hasEntry   | setEntry |
| hasIndex   | setMethod |
| hasItem    | supplier |
| index      | unknown |
| isEmpty    | unsetMethod |
| items      |        |
```

**Note:** The Directory class also has available class methods that metaclass, the **Class class**, defines. It also inherits methods from the **Map Collection class**, although there are not currently any methods defined in that class.

In addition to the standard put() and at() methods defined for Collections, Directories provide access to objects using methods. For example:

```rexx
define mydir = .directory~new
define mydir~name = "Mike"  -- same as mydir~put("Mike", "NAME")
say mydir~name             -- same as say mydir['NAME']
```

### 5.3.9.1. Inherited Methods

Methods inherited from the **Object class**.

```
new (class method) instanceMethod send
= \= \== \<> \>
instanceMethods sendWith
class isA setMethod
copy isInstanceOf start
defaultName objectName startWith
hasMethod objectName= string
```
Chapter 5. The Builtin Classes

Methods inherited from the Collection class.

[]    hasIndex    put
[]=   hasItem    subset
allIndexes   index    supplier
allItems   intersection    union
at    items   xor
difference    makeArray

Methods inherited from the MapCollection class.

putAll

5.3.9.2. new (Class Method)

>>-new---------------------------------------------------------><

Returns an empty Directory object.

5.3.9.3. []

>>-[name]------------------------------------------------------><

Returns the item corresponding to name. This method is the same as the at method.

5.3.9.4. [=

>>-[name]=item-------------------------------------------------><

Adds or replaces the entry at index name. This method is the same as the put method.

5.3.9.5. allIndexes

>>-allIndexes--------------------------------------------------><

Returns an array of all the directory indexes, including those of all the setMethod methods.

5.3.9.6. allItems

>>-allItems--------------------------------------------------------><

Returns an array of all items contained in the directory, including those returned by all setMethod methods.
5.3.9.7. at

Returns the item associated with index name. If a method defined using setMethod is associated with index name, the result of running this method is returned. If the collection has no item or method associated with index name, the Nil object is returned.

Example:

```rexx
say .environment"at("OBJECT") /* Produces: "The Object class" */
```

5.3.9.8. empty

Removes all items from the directory. Empty also removes all methods added using setMethod.

5.3.9.9. entry

Returns the directory entry with name name (translated to uppercase). If there is no such entry, name returns the item for any method that setMethod supplied. If there is neither an entry nor a method for name the Nil object is returned.

5.3.9.10. hasEntry

Returns 1 (true) if the directory has an entry or a method for name name (translated to uppercase), or 0 (false).

5.3.9.11. hasIndex

Returns 1 (true) if the collection contains any item associated with index name, or 0 (false).

5.3.9.12. hasItem

Returns 1 (true) if the collection contains the item at any index position or otherwise returns 0 (false). Item equality is determined by using the == method of item.
5.3.9.13. **index**

```plaintext
>>-index(item)-------------------------------------------------><
```

Returns the index of the specified item within the directory. If the target item appears at more than one index, the first located index will be returned. If the directory does not contain the specified item, the Nil object is returned. Item equality is determined by using the == method of `item`.

5.3.9.14. **isEmpty**

```plaintext
>>-isEmpty-----------------------------------------------------><
```

Returns 1 (true) if the directory is empty. Returns 0 (false) otherwise.

5.3.9.15. **items**

```plaintext
>>-items-------------------------------------------------------><
```

Returns the number of items in the collection.

5.3.9.16. **makeArray**

```plaintext
>>-makeArray---------------------------------------------------><
```

Returns a single-index array containing the index objects. The array indexes range from 1 to the number of items. The collection items appear in the array in an unspecified order. (The program should not rely on any order.)

5.3.9.17. **put**

```plaintext
>>-put(item,name)----------------------------------------------><
```

Makes the object `item` a member item of the collection and associates it with index `name`. The new item replaces any existing item or method associated with index `name`.

5.3.9.18. **remove**

```plaintext
>>-remove(name)------------------------------------------------><
```

Returns and removes the member item with index `name` from a collection. If a method is associated with `setMethod` for index `name`, the method is removed and running the method is returned. If there is no item or method with index `name`, the Nil object is returned.
5.3.9.19. removeItem

`-removeItem(item)`

Removes an item from the directory. If the target item exists at more than one index, the first located item is removed. The return value is the removed item. Item equality is determined by using the `==` method of `item`.

5.3.9.20. setEntry

`-setEntry(name-+--------+-)`

Sets the directory entry with name `name` (translated to uppercase) to the object `entry`, replacing any existing entry or method for `name`. If you omit `entry`, this method removes any entry or method with this `name`.

5.3.9.21. setMethod

`-setMethod(name-+---------+-)`

Associates entry name `name` (translated to uppercase) with method `method`. Thus, the object returns the result of running `method` when you access this entry. This occurs when you specify `name` on the at, entry, or remove method. This method replaces any existing item or method for `name`.

You can specify the name "UNKNOWN" as `name`. Doing so supplies a method that is run whenever an at() or entry() message specifies a name for which no item or method exists in the collection. This method’s first argument is the specified directory index. This method has no effect on the action of any hasEntry, hasIndex, items, remove, or supplier message sent to the collection.

The `method` can be a string containing a method source line instead of a method object. Alternatively, an array of strings containing individual method lines can be passed. In either case, an equivalent method object is created.

If you omit `method`, setMethod() removes the entry with the specified `name`.

5.3.9.22. supplier

`-supplier` 

Returns a `Supplier` object for the collection. The supplier allows you to iterate over the index/item pairs in the directory at the time the supplier was created. The supplier iterates the items in an unspecified order.

5.3.9.23. unknown

`-unknown(messageName,messageArgs)`

The unknown method is called when an at() or entry() message specifies a name for which no item or method exists in the collection.
Chapter 5. The Builtin Classes

Runs either the entry or setEntry method, depending on whether messagename ends with an equal sign. If messagename does not end with an equal sign, this method runs the entry() method, passing messagename as its argument. The messageargs argument is ignored. The entry() method is the return result.

If messagename does end with an equal sign, this method runs the setEntry() method, passing the first part of messagename (up to, but not including, the final equal sign) as its first argument, and the first item in the array messageargs as its second argument. In this case, unknown() returns no result.

5.3.9.24. unsetMethod

>>>-unsetMethod(name)-------------------------------------------><

Removes the association between entry name name (translated to uppercase) and a method.

5.3.9.25. xor

>>>-xor(argument)-----------------------------------------------><

Returns a new Directory object containing all items from the receiver collection and the argument collection; all indexes that appear in both collections are removed. The argument can be any collection class object. The argument must also allow all of the index values in the receiver collection.

5.3.9.26. Examples

/******************************************************************************/
/* A Phone Book Directory program */
/* This program demonstrates use of the directory class. */
/******************************************************************************/

/* Define an UNKNOWN method that adds an abbreviation lookup feature. */
/* Directories do not have to have an UNKNOWN method. */
book = .directory~new~~setMethod("UNKNOWN", .methods["UNKNOWN"])

book["ANN"] = "Ann B. ....... 555-6220"
book["ann"] = "Little annie . 555-1234"
book["JEFF"] = "Jeff G. ...... 555-5115"
book["MARK"] = "Mark C. ....... 555-5017"
book["MIKE"] = "Mike H. ...... 555-6123"
book["Rick"] = "Rick M. ....... 555-5110" /* Same as book["RICK"] = */

Do i over book /* Iterate over the collection */
    Say book[i]
end i

Say "" /* Index lookup is case sensitive... */
Say book~entry("Mike") /* ENTRY method uppercases before lookup */
Say book["ANN"] /* Exact match */
Say book~ann /* Message sends uppercase before lookup */
Chapter 5. The Builtin Classes

Say book["ann"] /* Exact match with lowercase index */
 Say ""
 Say book["M"] /* Uses UNKNOWN method for lookup */
 Say book["Z"]
 Exit

/* Define an unknown method to handle indexes not found. */
/* Check for abbreviations or indicate listing not found */
::Method unknown
 Parse arg at_index
 value = ""
 Do i over self
   If abbrev(i, at_index) then do
     If value <> "" then value = value", "
     value = value || self~at(i)
   end
 end i
 If value = "" then value = "No listing found for" at_index
 Return value

5.3.10. The List Class

A list is a non-sparse sequenced collection similar to the Array Class to which you can add new items at any position in the sequence. The List creates a new index value whenever an item is added to the list and the associated index value remains valid for that item regardless of other additions or removals. Only indexes the list object generates are valid i.e. the list is never a sparse list and the list object will not modify indexes for items in the list.
Figure 5-20. The List class and methods

```
    Object
    └── List
        + OrderedCollection

        new  of

        allIndexes
        allItems
        append
        at, [ ]
        empty
        first
        firstItem
        hasIndex
        hasItem
        index
        insert
        isEmpty

        Items
        last
        lastItem
        makeArray
        next
        previous
        put, [ ]=
        remove
        removeItem
        section
        supplier
```
Note: The List class also has available class methods that its metaclass, metaclass, the Class class, defines. It also inherits methods from the Ordered Collection class, although there are not currently any methods defined in that class.

5.3.10.1. Inherited Methods

Methods inherited from the Object class.

- new (class method)
- = == \== <= >=
- class
- copy
- defaultName
- hasMethod
- identityHash
- init
- instanceMethod
- send
- instanceMethods
- sendWith
- isA
- isInstanceOf
- objectName
- objectName=
- start
- startWith
- setMethod
- Request
- unsetMethod
- Run

Methods inherited from the Collection class.

- []
- [[]]
- put
- hasIndex
- hasItem
- subset
- allIndexes
- index
- supplier
- allItems
- intersection
- union
- at
- items
- xor
- difference
- makeArray

Methods inherited from the OrderedCollection class.

- append
- intersection
- xor
- appendAll
- subset
- difference
- union

5.3.10.2. new (Class Method)

```
>>-new----------------------------------------------------------><
```

Returns a new empty List object.

5.3.10.3. of (Class Method)

```
+-,----+
\ | 
>>-of(--item-->)--------------------------------------------------------------------------=<
```

Returns a newly created list containing the specified item objects in the order specified.
5.3.10.4. []

>>>-[index]--------------------------------------------------------------------<

Returns the item located at index. This is the same as the at method.

5.3.10.5. []=

>>>-[index]=item------------------------------------------------------------><

Replaces the item at index with item. This method is the same as the put method.

5.3.10.6. allIndexes

>>>-allIndexes---------------------------------------------------------------><

Returns an array of all indexes contained in the list in the same order they are used in the list.

5.3.10.7. allItems

>>>-allItems----------------------------------------------------------------><

Returns an array of all items contained in the list in list iteration order.

5.3.10.8. append

>>>-append(item)---------------------------------------------------------------><

Appends item to the end of the list, returning the index associated with item.

5.3.10.9. at

>>>-at(index)------------------------------------------------------------------><

Returns the item associated with index index. Returns the Nil object if the list has no item associated with index.

5.3.10.10. empty

>>>-empty---------------------------------------------------------------------><

Removes all items from the list.
5.3.10.11. first

`first` function returns the index of the first item in the list or the Nil object if the list is empty.

5.3.10.12. firstItem

`firstItem` function returns the first item in the list or the Nil object if the list is empty.

Example:

```oorexx
musketeers = .list~of(Porthos, Athos, Aramis) /* Creates list MUSKETEERS */
item = musketeers~firstItem /* Gives first item in list */
/* (Assigns "Porthos" to item) */
```

5.3.10.13. hasIndex

`hasIndex` function returns 1 (true) if the list contains any item associated with `index`, or 0 (false).

5.3.10.14. hasItem

`hasItem` function returns 1 (true) if the list contains the `item` at any index position or otherwise returns 0 (false). Item equality is determined by using the == method of `item`.

5.3.10.15. index

`index` function returns the index of the specified item within the list. If the target item appears at more than one index, the first located index will be returned. Returns the Nil object if the list does not contain the specified item. Item equality is determined by using the == method of `item`.

5.3.10.16. insert

`insert` function inserts the specified `item` at the specified `index`. If the `index` is not provided, the item is inserted at the end of the list.
Chapter 5. The Builtin Classes

Returns a list-supplied index for item item, which is added to the list. The inserted item follows an existing item with index index in the list ordering. If index is the Nil object, item becomes the first item in the list. If you omit index, the item becomes the last item in the list.

Inserting an item in the list at position index will cause the items in the list after position index to have their relative positions shifted by the list object. The index values for any items in the list are not modified by the insertion.

musketeers=.list~of(Porthos,Athos,Aramis) /* Creates list MUSKETEERS */
 /* consisting of: Porthos */
 /* Athos */
 /* Aramis */
index=musketeers~first /* Gives index of first item */
musketeers~insert("D'Artagnan",index) /* Adds D'Artagnan after Porthos */
 /* List is now: Porthos */
 /* D'Artagnan */
 /* Athos */
 /* Aramis */

/* Alternately, you could use */
musketeers~insert("D'Artagnan",.nil) /* Adds D'Artagnan before Porthos */
 /* List is now: D'Artagnan */
 /* Porthos */
 /* Athos */
 /* Aramis */

/* Alternately, you could use */
musketeers~insert("D'Artagnan") /* Adds D'Artagnan after Aramis */
 /* List is now: Porthos */
 /* Athos */
 /* Aramis */
 /* D'Artagnan */

5.3.10.17. isEmpty

>>-isEmpty-----------------------------------------------------><

Returns 1 (true) if the list is empty. Returns 0 (false) otherwise.

5.3.10.18. items

>>-items-------------------------------------------------------><

Returns the number of items in the list.

5.3.10.19. last

>>-last--------------------------------------------------------><

Returns the index of the last item in the list or the Nil object if the list is empty.
Chapter 5. The Builtin Classes

5.3.10.20. lastItem

>-lastItem----------------------------------------------------><

Returns the last item in the list or the Nil object if the list is empty.

5.3.10.21. makeArray

>-makeArray---------------------------------------------------><

Returns a single-index array containing the list collection items. The array indexes range from 1 to the number of items. The order in which the collection items appear in the array is the same as their sequence in the list collection.

5.3.10.22. next

>-next(index)-------------------------------------------------><

Returns the index of the item that follows the list item having index index. Returns the Nil object if index is the end of the list.

5.3.10.23. previous

>-previous(index)---------------------------------------------><

Returns the index of the item that precedes the list item having index index. Returns the Nil object if index is the beginning of the list.

5.3.10.24. put

>-put(item,index)---------------------------------------------><

Replaces any existing item associated with the specified index with the item. If index does not exist in the list, an error is raised.

5.3.10.25. remove

>-remove(index)------------------------------------------------<

Returns and removes from a collection the member item with index index. If no item has index index, this method returns the Nil object and removes no item.

Removing an item from the list at position index will shift the relative position of items after position index. The index values assigned to those items will not change.
Chapter 5. The Built-in Classes

5.3.10.26. removeItem

>>-removeItem(item)--------------------------------------------><

Removes an item from the list. If the target item exists at more than one index, the first located item is removed. The return value is the removed item. Item equality is determined by using the == method of item.

5.3.10.27. section

>>-section(start-+--------+-)----------------------------------><

Returns a new list (of the same class as the receiver) containing selected items from the receiver list. The first item in the new list is the item corresponding to index start in the receiver list. Subsequent items in the new list correspond to those in the receiver list (in the same sequence). If you specify the whole number items, the new list contains only this number of items (or the number of subsequent items in the receiver list, if this is less than items). If you do not specify items, the new list contains all subsequent items from the receiver list. The receiver list remains unchanged.

5.3.10.28. supplier

>>-supplier----------------------------------------------------><

Returns a Supplier object for the list. The supplier allows you to iterate over the index/item pairs stored in the list at the time the supplier is created. The iteration is in the same order as the list sequence order.

5.3.11. The Properties Class

A properties object is a collection with unique indexes that are character strings representing names and items that are also restricted to character string values. Properties objects are useful for processing bundles of application option values.
Figure 5-21. The Properties class and methods

<table>
<thead>
<tr>
<th>Object</th>

<tr>
<td><code>setProperty</code></td>
</tr>
<tr>
<td><code>setWhole</code></td>
</tr>
</tbody>
</table>

**Note:** The Properties class also has available class methods that its metaclass, the Class class, defines.

### 5.3.11.1. Inherited Methods

Methods inherited from the **Object class**.

- `new (class method)`
- `=`
- `<=`  
- `==`
- `<>`
- `instanceMethod`
- `instanceMethods`
- `send`
- `sendWith`
- `class`
- `isA`
- `sendWith`
- `copy`
- `isInstanceOf`
- `start`
- `defaultName`
- `objectName`
- `startTime`
- `hasMethod`
- `objectName=`
- `string`
- `identityHash`
- `Request`
- `unsetMethod`
- `init`
- `Run`

Methods inherited from the **Collection class**.

- `[]`
- `hasIndex`
- `put`
- `[]=`
- `hasItem`
- `subset`
- `allIndexes`
- `index`
- `supplier`
- `allItems`
- `intersection`
- `union`
- `at`
- `items`
- `xor`
- `difference`
- `makeArray`

Methods inherited from the **MapCollection class**.
putAll

Methods inherited from the Directory class.

allIndexes  hasIndex    [ ]=
allItems     hasItem     remove
at           index       removeItem
[ ]          isEmpty     setEntry
empty        items       setMethod
entry        makeArray   supplier
hasEntry     put         unsetMethod

5.3.11.2. load (Class method)

>>-load(source)----------------------------------------------------------><

Loads a set of properties from source and returns them as a new Properties object. The load source can be either the string name of a file or a stream object. Properties are read from the source as individual lines using linein(). Blank lines and lines with a Rexx line comment ("--") as the first non-blank characters are ignored. Otherwise, the lines are assumed to be of the form "name=value" and are added to the receiver Properties value using name as the index for the value.

5.3.11.3. new (Class method)

>>-new---------------------------------------------------------><

Returns an empty Properties object.

5.3.11.4. []=

>>-[name]=item--------------------------------------------------------><

Adds item using the index index. This method is the same as the put() method.

5.3.11.5. getLogical

>>-getLogical(name-+----------+-)--------------------------------------><
  +-default-+

Returns the value of name as either .true or .false. The raw value of the name may be either the numeric values "0" or "1" or the string values "true" or "false". Any other value will raise a syntax error. If the property name does not exist and default has been specified, the default value will be returned. If default has not been specified, a syntax error is raised for missing values.
Chapter 5. The Builtin Classes

5.3.11.6. getProperty

```cpp
getProperty(name---+-)-----------------------------><
+-,default+-
```

Returns the value of `name`. If property `name` does not exist and `default` has been specified, the default value will be returned. If `default` has not been specified, the Nil object is returned.

5.3.11.7. getWhole

```cpp
getWhole(name---+-)--------------------------------><
+-,default+-
```

Returns the value of `name`, validated as being a Rexx whole number. If property `name` does not exist and `default` has been specified, the default value will be returned. If `default` has not been specified, a syntax error is raised for missing values.

5.3.11.8. load

```cpp
load(source)------------------------------------------------><
```

Loads a set of properties into the receiving Properties object from `source`. The load source can be either the string name of a file or a stream object. Properties are read from the source as individual lines using `linein()`. Blank lines and lines with a Rexx line comment ("--") as the first non-blank characters are ignored. Otherwise, the lines are assumed to be of the form "name=value" and are added to the receiver Properties value using name as the index for the value. Properties loaded from `source` that have the same names as existing items will replace the current entries.

5.3.11.9. put

```cpp
put(item,name)----------------------------------------------><
```

Makes the object `item` a member item of the collection and associates it with index `name`. The item value must be a character string. The new item replaces any existing item or method associated with index `name`.

5.3.11.10. save

```cpp
save(target)------------------------------------------------><
```

Saves a set of properties into `target`. The save target can be either the string name of a file or a stream object. Properties are stored as individual lines using `lineout()`. The lines are written in the form "name=value". A saved Properties file can be reloaded using the Properties `load()` method.
5.3.11.11. setLogical

>>-setLogical(name,value)--------------------------------------><

Sets a logical value in the property bundle. The value argument must be either the numbers "0" or "1", or the logical values .true or .false. The property value will be added with value converted in to the appropriate "true" or "false" string value.

5.3.11.12. setProperty

>>-setProperty(name,value)-------------------------------------><

Sets a named property in the property bundle. The value argument must be a character string value.

5.3.11.13. setWhole

>>-setWhole(name,value)----------------------------------------><

Sets a whole number value in the property bundle. The value argument must be a valid Rexx whole number.

5.3.12. The Queue Class

A queue is a non-sparse sequenced collection with whole-number indexes. The indexes specify the position of an item relative to the head (first item) of the queue. Adding or removing an item changes the association of an index to its queue item. You can add items at either the tail or the head of the queue.
Chapter 5. The Built-in Classes

Figure 5-22. The Queue class and methods

<table>
<thead>
<tr>
<th>Object</th>
<th>Queue</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>+ OrderedCollection</td>
</tr>
<tr>
<td>new</td>
<td></td>
</tr>
<tr>
<td>of</td>
<td></td>
</tr>
</tbody>
</table>

| allIndexes | last |
| allItems   | makeArray |
| append     | next |
| at, []     | peek |
| empty      | previous |
| first      | pull |
| hasIndex   | push |
| hasItem    | put, []= |
| index      | queue |
| insert     | remove |
| isEmpty    | removeItem |
| items      | supplier |

Note: The Queue class also has available class methods that its metaclass, the Class class, defines. It also inherits methods from the Ordered Collection class.

5.3.12.1. Inherited Methods

Methods inherited from the Object class.

| new (class method) | instanceMethod | send |
|                   | instanceMethods | sendWith |
| class             | isA             | setMethod |
| copy              | isInstanceOf    | start |
| defaultName       | objectName      | startWith |
| hasMethod         | objectName=     | string |
| identityHash      | Request         | unsetMethod |
| init              | Run             |       |

Methods inherited from the Collection class.
Chapter 5. The Built-in Classes

Methods inherited from the OrderedCollection class.

Append intersection xor
appendAll subset
difference union

5.3.12.2. new (Class Method)

>>>new---------------------------------------------------------><

Returns a new empty Queue object.

5.3.12.3. of (Class Method)

\[\]

Returns a newly created queue containing the specified item objects in the order specified.

5.3.12.4. []

>>>-[index]---------------------------------------------------><

Returns the item located at index index. This is the same as the at() method.

5.3.12.5. []=

>>>-[index]=item-------------------------------------------------><

Replaces item at index with item. This method is the same as the put() method.

5.3.12.6. allIndexes

>>>allIndexes-------------------------------------------------------><

Returns an array of all index values for the queue. For the Queue class, the indices are integers 1 - items.
5.3.12.7. allItems

Returns an array of all items contained in the queue, in queue order.

5.3.12.8. append

Appends item to the end of the queue, returning the index of the inserted item.

5.3.12.9. at

Returns the item associated with index index. Returns the Nil object if the collection has no item associated with index.

5.3.12.10. empty

Removes all items from the queue.

5.3.12.11. first

Returns the index of the first item in the queue or the Nil object if the queue is empty. The index will always be 1 for non-empty queues.

5.3.12.12. hasIndex

Returns 1 (true) if the queue contains any item associated with index index, or 0 (false).

5.3.12.13. hasItem

Returns 1 (true) if the queue contains the item at any index position or otherwise returns 0 (false). Item equality is determined by using the == method of item.
5.3.12.14. index

```rexx
>>-index(item)------------------------------------------------------>

Returns the index of the specified item within the queue. If the target item appears at more than one index, the first located index will be returned. Returns the Nil object if the queue does not contain the specified item. Item equality is determined by using the == method of item.
```

5.3.12.15. insert

```rexx
>>-insert(item+--------+-)------------------------------------><
+-,index+-

Returns a queue-supplied index for item, which is added to the queue. The inserted item follows any existing item with index index in the queue ordering. If index is the Nil object, item is inserted at the head of the queue. If you omit index, item becomes the last item in the queue.

Inserting an item in the queue at position index will cause the items in the queue after position index to have their indexes modified by the queue object.

```rexx
musketeers=.queue~of(Porthos,Athos,Aramis) /* Creates queue MUSKETEERS */ /* consisting of: Porthos */ /* Athos */ /* Aramis */
index=musketeers~first /* Gives index of first item */
musketeers~insert("D'Artagnan",index) /* Adds D'Artagnan after Porthos */ /* List is now: Porthos */ /* D'Artagnan */ /* Athos */ /* Aramis */

/* Alternately, you could use/*/ musketeers~insert("D'Artagnan",.nil) /* Adds D'Artagnan before Porthos */ /* List is now: D'Artagnan */ /* Porthos */ /* Athos */ /* Aramis */

/* Alternately, you could use/*/ musketeers~insert("D'Artagnan") /* Adds D'Artagnan after Aramis */ /* List is now: Porthos */ /* Athos */ /* Aramis */ /* D'Artagnan */```

5.3.12.16. isEmpty

```rexx
>>-isEmpty-------------------------------------------------------->

Returns 1 (true) if the queue is empty. Returns 0 (false) otherwise.
```
5.3.12.17. items

Returns the number of items in the collection.

5.3.12.18. last

Returns the index of the last item in the queue or the Nil object if the queue is empty.

5.3.12.19. makeArray

Returns a single-index array containing the receiver queue items. The array indexes range from 1 to the number of items. The order in which the queue items appear in the array is the same as their queuing order, with the head of the queue as index 1.

5.3.12.20. next

Returns the index of the item that follows the queue item having index \textit{index} or returns the Nil object if the item having that index is last in the queue.

5.3.12.21. peek

Returns the item at the head of the queue. Returns the Nil object if the queue is empty. The collection remains unchanged.

5.3.12.22. previous

Returns the index of the item that precedes the queue item having index \textit{index} or the Nil object if the item having that index is first in the queue.

5.3.12.23. pull
Chapter 5. The Builtin Classes

Returns and removes the item at the head of the queue. Returns the Nil object if the queue is empty.

5.3.12.24. push

>>>-push(item)--------------------------------------------------><

Adds the object item to the head of the queue.

5.3.12.25. put

>>>-put(item,index)---------------------------------------------><

Replaces any existing item associated with the specified index with the new item. If the index does not exist in the queue, an error is raised.

5.3.12.26. queue

>>>-queue(item)-------------------------------------------------><

Adds the object item to the tail of the queue.

5.3.12.27. remove

>>>-remove(index)-----------------------------------------------><

Returns and removes from a collection the member item with index index. Returns the Nil object if no item has index index.

5.3.12.28. removeItem

>>>-removeItem(item)--------------------------------------------><

Removes an item from the queue. If the target item exists at more than one index, the first located item is removed. The return value is the removed item. Item equality is determined by using the == method of item.

5.3.12.29. supplier

>>>-supplier----------------------------------------------------><

Returns a Supplier object for the queue. The supplier allows you to iterate over the index/item pair contained in the queue at the time the supplier was created. The supplier iterates the items in their queuing order, with the head of the queue first.
5.3.13. The Relation Class

A relation is a collection with indexes that can be any object. In a relation, each item is associated with a single index, but there can be more than one item with the same index (unlike a table, which can contain only one item for any index).

Figure 5-23. The Relation class and methods

<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relation</td>
</tr>
<tr>
<td>+ MapCollection</td>

<td>Request</td>
<td>unsetMethod</td>
</tr>
</tbody>
</table>
init
Run

Methods inherited from the Collection class.

[] hasIndex put
[]?= hasItem subset
allIndexes index supplier
allItems intersection union
at items xor
difference makeArray

Methods inherited from the MapCollection class.

putAll

5.3.13.2. new (Class Method)

>>>-new--------------------------------------------------------><

Returns an empty Relation object.

5.3.13.3. []

>>>-[index]----------------------------------------------------><

Returns an item associated with index. This is the same as the at() method.

5.3.13.4. []=

>>>-[index]=item------------------------------------------------><

Adds item to the relation associated with index index. This is the same as the put() method.

5.3.13.5. allAt

>>>-allAt(index)------------------------------------------------><

Returns a single-index array containing all the items associated with index index. Items in the array appear in an unspecified order. Index equality is determined by using the == method of index.

5.3.13.6. allIndex

>>>-allIndex(item)------------------------------------------------><

Returns a single-index array containing all indexes for item item, in an unspecified order. Item equality is determined by using the == method of item.
5.3.13.7. allIndexes

Returns an array of all indexes contained in the Relation. The returned array will have one index for every item stored in the relation, including duplicates. Duplicate indexes can be removed easily by converted the array to a set.

```rexx
code
    -- retrieve the unique index items
    indexes = .set`new`union(relation`allindexes)
```

5.3.13.8. allItems

Returns an array of all items contained in the relation.

5.3.13.9. at

Returns the item associated with index `index`. If the relation contains more than one item associated with index `index`, the item returned is unspecified. (The program should not rely on any particular item being returned.) Returns the Nil object if the relation has no item associated with index `index`. Index equality is determined by using the `==` method of `index`.

5.3.13.10. difference

Returns a new Relation containing only those items that the `argument` collection does not contain (with the same associated index). The `argument` can be any collection class object.

5.3.13.11. empty

Removes all items from the relation.

5.3.13.12. hasIndex

Returns 1 (true) if the collection contains any item associated with index `index`, or 0 (false). Index equality is determined by using the `==` method of `index`.
5.3.13.13. hasItem

```
>>-hasItem(item+-)-----------------------------------------><
  +-index+-
```

Returns 1 (true) if the relation contains the member item item, 0 (false). If index is specified, hasIndex() will only return true if the relation contains the pairing of item associated with index index. Item and index equality is determined by using the == method.

5.3.13.14. index

```
>>-index(item)-------------------------------------------------><
```

Returns the index for item item. If there is more than one index associated with item item, the one returned is not defined. Item equality is determined by using the == method of item.

5.3.13.15. intersection

```
>>-intersection(argument)--------------------------------------><
```

Returns a new collection (of the same class as the receiver) containing only those items that are in both the receiver collection and the argument collection with the same associated index. The argument can be any collection class object.

5.3.13.16. isEmpty

```
>>-isEmpty-----------------------------------------------------><
```

Returns 1 (true) if the relation is empty. Returns 0 (false) otherwise.

5.3.13.17. items

```
>>-items-(index)--
```

Returns the number of relation items with index index. If you specify no index, this method returns the total number of items associated with all indexes in the relation. Index equality is determined by using the == method of index.

5.3.13.18. makeArray

```
>>-makeArray---------------------------------------------------><
```

Returns a single-index array containing the index objects. The collection items appear in the array in an unspecified order.
5.3.13.19. put

>>-put(item,index)--------------------------------------------><

Makes the object item a member item of the relation and associates it with index index. If the relation already contains any items with index index, this method adds a new member item item with the same index, without removing any existing member items.

5.3.13.20. remove

>>-remove(index)----------------------------------------------><

Returns and removes from a relation the member item with index index. If the relation contains more than one item associated with index index, the item returned and removed is unspecified. Returns the Nil object if no item has index index. Index equality is determined by using the == method of index.

5.3.13.21. removeItem

>>-removeItem(item,index)--------------------------------------><

Returns and removes from a relation the member item item (associated with index index). Returns the Nil object if value is not a member item associated with index index. If item is the only member with index) then the index) is also removed from the Relation.

5.3.13.22. subset

>>-subset(argument)--------------------------------------------><

Returns 1 (true) if all items in the receiver Relation are also contained in the argument collection with the same associated index; returns 0 (false) otherwise. The argument can be any collection class object.

5.3.13.23. supplier

>>-supplier+-+---------+--------------------------------------><

+(index)--

Returns a The Supplier Class object for the relation. The supplier allows you to iterate over all index/item pairs in the relation at the time the supplier was created. The supplier enumerates the items in an unspecified order. If you specify index, the supplier contains all of the items with the specified index.

5.3.13.24. union

>>-union(argument)--------------------------------------------><

Returns a new collection containing all items from the receiver collection and the argument collection. The argument can be any collection class object.
5.3.13.25. xor

>>-xor(argument)-----------------------------------------------><

Returns a new collection of the same class as the receiver that contains all items from the receiver collection and the argument collection. All index-item pairs that appear in both collections are removed. The argument can be any collection class object.

5.3.13.26. Examples

/* Use a relation to express parent-child relationships */
family = .relation~new
family["Henry"] = "Peter" /* Peter is Henry's child */
family["Peter"] = "Bridget" /* Bridget is Peter's child */
family["Henry"] = "Jane" /* Jane is Henry's child */

/* Show all children of Henry recorded in the family relation */
henrys_kids = family~allAt("Henry")
Say "Here are all the listed children of Henry:"
Do kid Over henrys_kids
    Say " kid"
End

/* Show all parents of Bridget recorded in the family relation */
bridgets_parents = family~allIndex("Bridget")
Say "Here are all the listed parents of Bridget:"
Do parent Over bridgets_parents
    Say " parent"
End

/* Display all the grandparent relationships we know about. */
checked_for_grandkids = .set~new /* Records those we have checked */
Do grandparent Over family /* Iterate for each index in family */
    If checked_for_grandkids~hasIndex(grandparent)
        Then Iterate /* Already checked this one */
kids = family~allAt(grandparent) /* Current grandparent's children */
    Do kid Over kids /* Iterate for each item in kids */
        grandkids = family~allAt(kid) /* Current kid's children */
        Do grandkid Over grandkids /* Iterate for each item in grandkids */
            Say grandparent "has a grandchild named" grandkid"."
        End
    End
    checked_for_grandkids~put(grandparent) /* Add to already-checked set */
End
5.3.14. The Set Class

A Set is a collection containing member items where the index is the same as the item (similar to a Bag collection). Any object can be placed in a set. There can be only one occurrence of any object in a set (unlike a Bag collection). Item equality is determined by using the == method.

Figure 5-24. The Set class and methods

Note: The Set class also has available class methods that its metaclass, the Class class, defines.

The Set class is a subclass of the Table class. In addition to its own methods, it inherits the methods of the Object class (see The Object Class) and the Table class. It also inherits methods from the Set Collection class.

5.3.14.1. Inherited Methods

Methods inherited from the Object class.

new (class method)  instanceMethod  send
= <= \= <> >>  instanceMethods  sendWith
copy  isA  setMethod
defaultName  isInstanceOf  start
objectName  startWith
Methods inherited from the Collection class.

[] hasIndex put
[]= hasItem subset
allIndexes index supplier
allItems intersection union
at items xor
difference makeArray

Methods inherited from the MapCollection class.

putAll

Methods inherited from the Table class.

new (class method) hasIndex put
allIndexes hasItem []=
allItems index remove
at isEmpty removeItem
[] items supplier
empty makeArray

5.3.14.2. of (Class Method)

\[+,------\]
\[\|\]
\[>>-of(---item+-)----------------------------------------------><\]

Returns a newly created set containing the specified item objects.

5.3.14.3. []=

\[>>-[index]=item-----------------------------------------------><\]

Add an item to the Set. This method is the same as the put() method.

5.3.14.4. intersection

\[>>-intersection(argument)--------------------------------------><\]

Returns a new collection (of the same class as the receiver) containing only those items from the receiver whose indexes are in both the receiver collection and the argument collection. The argument can be any collection class object. The argument must also allow all of the index values in the receiver collection.
Chapter 5. The Builtin Classes

5.3.14.5. put

>>-put(item+-+--------+-)------------------------------------------><
 +-,index+-

Adds item to the Set. If there is an equivalent item in the Set, the exiting item will be replaced by the new instance. Item equality is determined by using the == method of item. If index is specified, it must be the same as item.

5.3.14.6. putAll

>>-putAll(collection)------------------------------------------><

Adds all items collection to the target set. The collection argument can be any object that supports a supplier method. Items from collection are added using the item values returned by the supplier. If duplicate items exist in collection, the last item provided by the supplier will overwrite previous items with the same index.

5.3.14.7. subset

>>-subset(argument)------------------------------------------><

Returns 1 (true) if all items in the receiver collection are also contained in the argument collection; returns 0 (false) otherwise. The argument can be any collection class object. The argument must also allow all of the index values in the receiver collection.

5.3.14.8. union

>>-union(argument)------------------------------------------><

Returns a new Set contains all the items from the receiver collection and selected items from the argument collection. This method includes an item from argument in the new collection only if there is no item already in the in the receiver collection and the method has not already included a matching item. The order in which this method selects items in argument is unspecified. The argument can be any collection class object. The argument must also allow all of the index values in the receiver collection.

5.3.14.9. xor

>>-xor(argument)------------------------------------------><

Returns a new Set that contains all items from the receiver collection and the argument collection; all items that appear in both collections are removed. The argument can be any collection class object. The argument must also allow all of the index values in the receiver collection.
5.3.15. The Stem Class

A stem object is a collection with unique indexes that are character strings.

Figure 5-25. The Stem class and methods

<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stem</td>
</tr>
<tr>
<td>+ MapCollection</td>
</tr>
</tbody>
</table>

new

- <=  ==  <=  <>  <=  ><
- allIndexes
- allItems
- at, [ ]
- empty
- hasIndex
- hasItem
- index
- isEmpty

items
makeArray
put, [ ]=
remove
removeltem
request
supplier
toDirectory
unknown

Note: The Stem class also has available class methods that its metaclass, the Class class, defines. It also inherits methods from the Map Collection class.

Stems are automatically created whenever a Rexx stem variable or Rexx compound variable is used. For example:

```
a.1 = 2
```

creates a new stem collection with the name A. and assigns it to the Rexx variable A.; it also assigns the value 2 to entry 1 in the collection.

The value of an uninitialized stem index is the stem object NAME concatenated with the derived stem index. For example

```
say a.[1,2] -- implicitly creates stem object with name "A."
-- displays "A.1.2"
a = .stem"new("B.")
say a[1,2] -- displays "B.1.2"
```
Chapter 5. The Builtin Classes

In addition to the items explicitly assigned to the collection indexes, a value may be assigned to all possible stem indexes. The \[\]= method (with no index argument) will assign the target value to all possible stem indexes. Following assignment, a reference to any index will return the new value until another value is assigned or the index is dropped.

The \[\] method (with no index specified) will retrieve any globally assigned value. By default, this returns the stem NAME value.

In addition to the methods defined in the following, the Stem class removes the methods =, ==, \<=, \>=, <>, and >> using the DEFINE method.

5.3.15.1. Inherited Methods

Methods inherited from the Object class.

```plaintext
new (class method) instanceMethod send
\[\] \[\]= \[\] === \[\] \[\] \[\] <\> \[\]<
class isA sendWith
copy isInstanceOf start
defaultName objectName startWith
hasMethod objectName= string
identityHash Request unsetMethod
init Run
```

Methods inherited from the Collection class.

```plaintext
[] hasIndex put
[]= hasItem subset
allIndexes index supplier
allItems intersection union
at items xor
difference makeArray
```

Methods inherited from the MapCollection class.

```plaintext
putAll
```

5.3.15.2. new (Class Method)

```
>>>new+-+------------------------------------------------+<
   + (name)++
```

Returns a new stem object. If you specify a string name, this value is used to create the derived name of compound variables. The default stem name is a null string ("").

5.3.15.3. []

```
+-,----------------
 | v
>>>[+-+-----------]------------------------------------------------+<
   +index++
```
Returns the item associated with the specified indexes. Each index is an expression; use commas to separate the expressions. The Stem object concatenates the index string values, separating them with a period (.), to create a derived index. A null string (""") is used for any omitted expressions. The resulting string is the index of the target stem item. If the stem has no item associated with the specified final index, the stem default value is returned. If a default value has not been set, the stem name concatenated with the final index string is returned.

If you do not specify index, the stem default value is returned. If no default value has been assigned, the stem name is returned.

**Note:** You cannot use the [] method in a DROP or PROCEDURE instruction.

### 5.3.15.4. []=

```
+-,-,------------+
 |          \     |
V  |                  |
>>-[-------------+-]=value-------------------------------------><
   +-index+-
```

Makes the value a member item of the stem collection and associates it with the specified index. The final index is derived by concatenation each of the index arguments together with a "." separator. If you specify no index arguments, a new default stem value is assigned. Assigning a new default value will re-initialize the stem and remove all existing assigned indexes.

### 5.3.15.5. allIndexes

```
>>-allIndexes--------------------------------------------------><
```

Returns an array of all the stem tail names used in the stem.

### 5.3.15.6. allItems

```
>>-allItems----------------------------------------------------><
```

Returns an array of all items contained in the stem.

### 5.3.15.7. at

```
>>-at(tail)----------------------------------------------------><
```

Returns the item associated with the specified tail. The Nil object is returned if the stem has no item associated with the specified tail.
5.3.15.8. empty

>>>-empty------------------------------------------------------->>-

Removes all items from the stem.

5.3.15.9. hasIndex

>>>-hasIndex(tail)----------------------------------------------><

Returns 1 (true) if the collection contains any item associated with a stem tail tail, or 0 (false).

5.3.15.10. hasItem

>>>-hasItem(value)----------------------------------------------><

Returns 1 (true) if the collection contains the value at any tail position or otherwise returns 0 (false). Item equality is determined by using the == method of item.

5.3.15.11. index

>>>-index(item)------------------------------------------------)-->

Returns the index of the specified item within the stem. Returns the Nil object if the stem does not contain the specified item. Item equality is determined by using the == method of item.

5.3.15.12. isEmpty

>>>-isEmpty------------------------------------------------------>>-

Returns 1 (true) if the stem is empty. Returns 0 (false) otherwise.

5.3.15.13. items

>>>-items------------------------------------------------------>>-

Returns the number of items in the collection.

5.3.15.14. makeArray

>>>-makeArray-------------------------------------------------->>-

Returns an array of all stem indexes that currently have an associated value. The items appear in the array in an unspecified order.
5.3.15.15. put

>>-put(item,tail)----------------------------------------------><

Replaces any existing item associated with the specified tail with the new item item.

5.3.15.16. remove

>>-remove(tail)------------------------------------------------><

Returns and removes from the stem the member item with index tail. Returns the Nil object if no item has index tail.

5.3.15.17. removeItem

>>-removeItem(item)--------------------------------------------><

Removes an item from the stem. If the target item exists at more than one tail, the first located item is removed. Item equality is determined by using the == method of item. The return value is the removed item.

5.3.15.18. request

>>-request(classid)--------------------------------------------><

This method requests conversion to a specific class. All conversion requests except Array are forwarded to the stem’s current stem default value. Returns the result of the Stem class makeArray method, if the requested class is Array. For all other classes, request forwards the message to the stem object’s default value.

5.3.15.19. supplier

>>-supplier----------------------------------------------------><

Returns a Supplier object for the stem. The supplier allows you to iterate though the index/item pairs contained in the Stem object at the time the supplier was created. The supplier iterates the items in an unspecified order.

5.3.15.20. toDirectory

>>-toDirectory----------------------------------------------------><

Returns a Directory object for the stem. The directory will contain a name/value pair for each stem index with a directly assigned value.
Chapter 5. The Built-in Classes

5.3.15.21. unknown

>>>-unknown-\(\text{message name, message args}\)---------------------------><

Reissues or forwards all unknown messages to the stem’s current default value. For additional information, see Defining an unknown Method.

5.3.16. The Table Class

A table is a collection with indexes that can be any object. In a table, each item is associated with a single index, and there can be only one item for each index (unlike a relation, which can contain more than one item with the same index). Index equality is determined by using the $== method.

Figure 5-26. The Table class and methods

<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
</tr>
<tr>
<td>+ MapCollection</td>
</tr>
<tr>
<td>new</td>

<tr>
<td>allIndexes</td>
</tr>
<tr>
<td>allItems</td>
</tr>
<tr>
<td>at, [ ]</td>
</tr>
<tr>
<td>empty</td>
</tr>
<tr>
<td>hasIndex</td>
</tr>
<tr>
<td>hasItem</td>
</tr>
<tr>
<td>index</td>
</tr>
</tbody>
</table>

Note: The Table class also has available class methods that its metaclass, the Class class, defines. It also inherits methods from the Map Collection class.

5.3.16.1. Inherited Methods

Methods inherited from the Object class.

new (class method)  instanceMethod  send
5.3.16.2. new (Class Method)

```
new
```

Returns an empty Table object.

5.3.16.3. []

```
[index]
```

Returns the item associated with index. This is the same as the at() method.

5.3.16.4. []=

```
[index]=item
```

Adds item to the table at index index. This method is the same as the put() method.

5.3.16.5. allIndexes

```
allIndexes
```

Returns an array of all indexes contained in the table.

5.3.16.6. allItems

```
allItems
```

Returns an array of all indexes contained in the table.
Returns an array of all items contained in the table.

5.3.16.7. at

\[ \texttt{at(index)} \]

Returns the item associated with index \textit{index}. Returns the Nil object if the collection has no item associated with \textit{index}.

5.3.16.8. empty

\[ \texttt{empty} \]

Removes all items from the table.

5.3.16.9. hasIndex

\[ \texttt{hasIndex(index)} \]

Returns \texttt{1} (true) if the collection contains any item associated with index \textit{index}, or \texttt{0} (false).

5.3.16.10. hasItem

\[ \texttt{hasItem(value)} \]

Returns \texttt{1} (true) if the collection contains the \textit{value} at any index position or otherwise returns \texttt{0} (false). Item equality is determined by using the \texttt{==} method of \textit{item}.

5.3.16.11. index

\[ \texttt{index(item)} \]

Returns the index of the specified item within the table. If the target item appears at more than one index, the first located index will be returned. Returns the Nil object if the table does not contain the specified item. Item equality is determined by using the \texttt{==} method of \textit{item}.

5.3.16.12. isEmpty

\[ \texttt{isEmpty} \]

Returns \texttt{1} (true) if the table is empty. Returns \texttt{0} (false) otherwise.
5.3.16.13. items

```-items-------------------------------------------------------><
```

Returns the number of items in the collection.

5.3.16.14. makeArray

```-makeArray---------------------------------------------------><
```

Returns a single-index array containing the index objects. The array indexes range from 1 to the number of items. The collection items appear in the array in an unspecified order.

5.3.16.15. put

```-put(item,index)---------------------------------------------><
```

Makes the object `item` a member item of the collection and associates it with index `index`. The new item replaces any existing items associated with index `index`.

5.3.16.16. remove

```-remove(index)-----------------------------------------------><
```

Returns and removes the table item with index `index`. Returns the Nil object if no item has index `index`.

5.3.16.17. removeItem

```-removeItem(item)--------------------------------------------><
```

Removes an item from the table. If the target item exists at more than one index, the first located item is removed. The return value is the removed item. Item equality is determined by using the `==` method of `item`.

5.3.16.18. supplier

```-supplier----------------------------------------------------><
```

Returns a Supplier object for the collection. The supplier allows you iterate over the index/item pairs contained in the table at the time the supplier was created. The supplier iterates over the items in an unspecified order.
5.3.17. The IdentityTable Class

An identity table is a collection with indexes that can be any object. In an identity table, each item is associated with a single index, and there can be only one item for each index. Index and item matches in an identity table are made using an object identity comparison. That is, an index will only match if the same instance is used in the collection.

Figure 5-27. The IdentityTable class and methods

<table>
<thead>
<tr>
<th>Object</th>

Methods inherited from the MapCollection class.

putAll

5.3.17.2. new (Class Method)

>>-new<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<< Returns an empty IdentityTable object.

5.3.17.3. []

>>-[index]<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<< Returns the item associated with index. This is the same as the at() method.

5.3.17.4. []=

>>-[index]=item<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<< Adds item to the table at index index. This method is the same as the put() method.

5.3.17.5. allIndexes

>>-allIndexes<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<< Returns an array of all indices contained in the table.

5.3.17.6. allItems

>>-allItems<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<< Returns an array of all items contained in the table.

5.3.17.7. at

>>-at(index)<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<
Chapter 5. The Builtin Classes

Returns the item associated with index index. Returns the Nil object if the collection has no item associated with index.

5.3.17.8. empty

>>-empty-------------------------------------------------------><

Removes all items from the table.

5.3.17.9. hasIndex

>>-hasIndex(index)---------------------------------------------><

Returns 1 (true) if the collection contains any item associated with index index, or 0 (false).

5.3.17.10. hasItem

>>-hasItem(item)-----------------------------------------------><

Returns 1 (true) if the collection contains the item at any index position or otherwise returns 0 (false).

5.3.17.11. index

>>-index(item)-------------------------------------------------><

Returns the index of the specified item within the table. If the target item appears at more than one index, the first located index will be returned. Returns the Nil object if the table does not contain the specified item.

5.3.17.12. isEmpty

>>-isEmpty-------------------------------------------------------><

Returns 1 (true) if the table is empty. Returns 0 (false) otherwise.

5.3.17.13. items

>>-items-------------------------------------------------------><

Returns the number of items in the collection.
5.3.17.14. **makeArray**

```clojure
>>-makeArray-----------------------------------------------><
```

Returns a single-index array containing the index objects. The array indexes range from 1 to the number of items. The collection items appear in the array in an unspecified order.

5.3.17.15. **put**

```clojure
>>-put(item,index)---------------------------------------------><
```

Makes the object *item* a member item of the collection and associates it with index *index*. The new item replaces any existing items associated with index *index*.

5.3.17.16. **remove**

```clojure
>>-remove(index)-----------------------------------------------><
```

Returns and removes from a collection the member item with index *index*. Returns the Nil object if no item has index *index*.

5.3.17.17. **removeItem**

```clojure
>>-removeItem(item)--------------------------------------------><
```

Removes an item from the table. If the target item exists at more than one index, the first located item is removed. The return value is the removed item.

5.3.17.18. **supplier**

```clojure
>>-supplier----------------------------------------------------><
```

Returns a Supplier object for the collection. The supplier allows you iterate over the index/item pairs contained in the table at the time the supplier was created. The supplier iterates over the items in an unspecified order.

5.3.18. **Sorting Arrays**

Any non-sparse Array instance can have its elements placed into sorted order using the sort method of the Array class. The simplest sort is sorting an array of strings. For example:

```rexx
myArray = .array~of("Zoe", "Fred", "Xavier", "Andy")
myArray~sort
do name over myArray
```
Chapter 5. The Builtin Classes

say name
end

will display the names in the order "Andy", "Fred", "Xavier", "Zoe".

The sort method orders the strings by using the compareTo method of the String class. The compareTo method knows how to compare one string to another, and returns the values -1 (less than), 0 (equal), or 1 (greater than) to indicate the relative ordering of the two strings.

5.3.18.1. Sorting non-strings

Sorting is not limited to string values. Any object that inherits the Comparable mixin class and implements a compareTo method can be sorted. The DateTime Class and TimeSpan Class are examples of built-in Rexx classes that can be sorted. Any user created class may also implement a compareTo() method to enable sorting. For example, consider the following simple class:

::class Employee inherit Comparable
::method init
  expose id name
  use arg id, name
::method id attribute
::method name attribute
::method compareTo
  expose id
  use arg other
  return id~compareTo(other~id) -- comparison performed using employee id
::method string
  expose name
  use arg name
  return "Employee" name

The Employee class implements its sort order using the employee identification number. When the sort method needs to compare two Employee instances, it will call the compareTo method on one of the instances, passing the second instance as an argument. The compareTo method tells the sort method which of the two instances should be first.

a = .array~new
a[1] = .Employee~new(654321, "Fred")
a[2] = .Employee~new(123456, "George")

a~sort

do employee over a
  say employee -- sorted order is "George", "William", "Fred"
end
5.3.18.2. Sorting with more than one order

The String class `compareTo` method only implements a sort ordering for an ascending sort using a strict comparison. Frequently it’s desirable to override a class-defined sort order or even to sort items that do not implement a `compareTo` method. To change the sorting criteria, use the Array `sortWith` method. The `sortWith` method takes a single argument, which is a Comparator object that implements a `compare` method. The `compare` method performs comparisons between pairs of items. Different comparators can be customized for different comparison purposes. For example, the Rexx language provides a DescendingComparator class that will sort items into descending order:

```rexx
::CLASS 'DescendingComparator' MIXINCLASS Comparator
::METHOD compare
use strict arg left, right
return -left~compareTo(right)
```

The DescendingComparator merely inverts the result returned by the item `compareTo` method. Our previous example

```rexx
myArray = .array~of("Zoe", "Fred", "Xavier", "Andy")
myArray~sortWith(.DescendingComparator~new)
```

```rexx
do name over myArray
   say name
end
```

now displays in the order "Zoe", "Xavier", "Fred", "Andy".

Custom Comparators are simple to create for any sorting purpose. The only requirement is implementing a `compare` method that knows how to compare pairs of items in some particular manner. For example, to sort our Employee class by name instead of the default employee id, we can use the following simple comparator class:

```rexx
::CLASS EmployeeNameSorter MIXINCLASS Comparator
::METHOD compare
use strict arg left, right
return left~name~compareTo(right~name) -- do the comparison using the names
```

5.3.18.3. Builtin Comparators

Rexx includes a number of built-in Comparators for common sorting operations.

**Comparator**

Base comparator. The Comparator class just uses the `compareTo` method of the first argument to generate the result. Using `sortWith` and a Comparator instance is equivalent to using the `sort` method and no comparator.

**DescendingComparator**

The reverse of the Comparator class. The DescendingComparator can be used to sort items in descending order.
InvertingComparator

The InvertingComparator will invert the result returned by another Comparator instance. This comparator can be combined with another comparator instance to reverse the sort order.

CaselessComparator

Like the base comparator, but uses the `caselessCompareTo` method to determine order. The String class implements `caselessCompareTo`, so the CaselessComparator can be used to sort arrays of strings independent of case.

ColumnComparator

The ColumnComparator will sort string items using specific substrings within each string item. If sorting is performed on multiple column positions, the `stableSortWith` method is recommended to ensure the results of previous sort operations are retained.

CaselessColumnComparator

Like the ColumnComparator, but the substring comparisons are done independently of case.

5.3.18.4. Stable and Unstable Sorts

The default sorting algorithm is a Quicksort. A Quicksort is a very efficient sorting algorithm that does not require any additional memory to implement. Unfortunately, a Quicksort is also an *unstable* sort. In an unstable sort, items are not guaranteed to maintain their original positions if they compare equal during the sort. Consider the following simple example:

```rexx
    a = .array~of("Fred", "George", "FRED", "Mike", "fred")
    a~sortwith(.caselesscomparator~new)
    do name over a
        say name
    end
```

This example displays the 3 occurrences of Fred in the order "Fred", "fred", "FRED", even though they compare equal using a caseless comparison.

The Array class implements a second sort algorithm that is available using the `stableSort` and `stableSortWith` methods. These methods use a Mergesort algorithm, which is less efficient than the default Quicksort and requires additional memory. The Mergesort is a stable algorithm that maintains the original relative ordering of equivalent items. Our example above, sorted with `stableSortWith`, would display "Fred", "FRED", "fred".

5.3.19. The Concept of Set Operations

The following sections describe the concept of set operations to help you work with set operators, in particular if the receiver collection class differs from the argument collection class.

Rexx provides the following set-operator methods:

- difference
Chapter 5. The Builtin Classes

• intersection
• subset
• union
• xor

These methods are available to instances of the following collection classes:

• The OrderedCollections Array, List, and Queue
• The MapCollections Directory, Stem, Table, and Relation
• The SetCollections Set and Bag.

\[
\text{result} = \text{receiver} \cdot \text{setoperator}(\text{argument})
\]

where:

receiver

is the collection object receiving the set-operator message.

setoperator

is the set-operator method used.

argument

is the argument collection supplier supplied to the method. It can be an instance of one of the Rexx collection classes or any object that implements a `makearray` method or `supplier` method, depending on class of receiver.

The result object is of the same class as the receiver collection object.

5.3.19.1. The Principles of Operation

A set operation is performed by iterating over the elements of the receiver collection to compare each element of the receiver with each element of the argument collection. The element is defined as the tuple `<index,item>` (see Determining the Identity of an Item). Depending on the set-operator method and the result of the comparison, an element of the receiver collection is, or is not, included in the resulting collection. A receiver collection that allows for duplicate elements can, depending on the set-operator method, also accept elements of the argument collection after they have been coerced to the type of the receiver collection.

The following examples are to help you understand the semantics of set operations. The collections are represented as a list of elements enclosed in curly brackets. The list elements are separated by a comma.

5.3.19.2. Set Operations on Collections without Duplicates

Assume that the example sets are \(A=\{a,b\}\) and \(B=\{b,c,d\}\). The result of a set operation is another set. The only exception is a subset resulting in a Boolean `.true` or `.false`. Using the collection \(A\) and \(B\), the different set operators produce the following:
UNION operation

All elements of A and B are united:
A UNION B = {a,b,c,d}

DIFFERENCE operation

The resulting collection contains all elements of the first set except for those that also appear in the second set. The system iterates over the elements of the second set and removes them from the first set one by one.
A DIFFERENCE B = {a}
B DIFFERENCE A = {c,d}

XOR operation

The resulting collection contains all elements of the first set that are not in the second set and all elements of the second set that are not in the first set:
A XOR B = {a,c,d}

INTERSECTION operation

The resulting collection contains all elements that appear in both sets:
A INTERSECTION B = {b}

SUBSET operation

Returns .true if the first set contains only elements that also appear in the second set, otherwise it returns .false:
A SUBSET B = .false
B SUBSET A = .false

5.3.19.3. Set-Like Operations on Collections with Duplicates

Assume that the example bags are A={a,b,b} and B={b,b,c,c,d}. The result of any set-like operation is a collection, in this case a bag. The only exception is subset resulting in a Boolean .true or .false. Using the collections A and B, the different set-like operators produce the following:

UNION operation

All elements of A and B are united:
A UNION B = {a,b,b,b,b,c,c,d}

DIFFERENCE operation

The resulting collection contains all elements of the first bag except for those that also appear in the second bag. The system iterates over the elements of the second bag and removes them from the first bag one by one.
A DIFFERENCE B = {a}
B DIFFERENCE A = {c,c,d}
Chapter 5. The Builtin Classes

XOR operation
The resulting collection contains all elements of the first bag that are not in the second bag and all
elements of the second bag that are not in the second bag:

A XOR B = \{a,c,c,d\}

INTERSECTION operation
The resulting collection contains all elements that appear in both bags:

A INTERSECTION B = \{b,b\}

SUBSET operation
Returns .true if the first set contains only elements that also appear in the second set, otherwise it
returns .false:

A SUBSET B = .false
B SUBSET A = .false

5.3.19.4. Determining the Identity of an Item

Set operations require the definition of the identity of an element to determine whether a certain element
exists in the receiver collection. The element of a collection is conceived as the tuple <index,item>. The
index is used as the identification tag associated with the item. Depending on the collection class, the
index is an instance of a particular class, for example, the string class for a directory element, an integer
for an array, or any arbitrary class for a relation. The Array class is an exception because it can be
multidimensional having more than one index. However, as a collection, it is conceptionally linearized
by the set operator.

For collection classes that require unique indexes, namely the Set, IdentityTable, Table, Directory, and
Stem, an item is identified by its index. For collections of collection classes that allow several items to
have the same index, namely the Relation class, an item is identified by both its index and its item. For
the Bag and the Set subclasses, where several items can have the same index but index and item must
be identical, the item is identified by its index. For Array, List, and Queue classes, the index is derived from
an object’s position within the collection’s order. Items are identified using only item.

When collections with different index semantics are used in set operations, the argument collection is
coerced into a collection of the same type as the receiver, and the operation is then performed using the
converted collection. The coercion process differs based on the types of both the receiver and the
argument collection. According to this concept, an item of a collection is identified for the different
receiver categories as follows:

Map Collection
If argument is a MapCollection, then index values are used to determine membership, and items are
inserted into the result using the index and item pairs.

If argument is an OrderedCollection or SetCollection, argument is converted into a MapCollection
using the collection items as both index and item values. Since the argument collection may contain
duplicate items, the converted collection is effectively a Relation instance.

For all other argument objects, the makearray method is used to obtain a set of values which are
used as if argument was an OrderedCollection.
Ordered Collection and Set Collection

If argument is an instance of Collection, the matching set is obtained from the `allItems` method. For any other class of object, the `makearray` method is used. The `hasItem` method is used to perform the matching operations between the two collections.

Relation

If argument is a MapCollection, then index values are used to determine membership, and items are inserted into the result using the index and item pairs.

If argument is an OrderedCollection or SetCollection, argument is converted into a MapCollection using the collection items as both index and item values. Since the argument collection may contain duplicate items, the converted collection is effectively a Relation instance.

For all other argument objects, the `makearray` method is used to obtain a set of values which are used as if argument was an OrderedCollection. All tests for result membership are made using both the index and item values.

5.4. The Utility Classes

This section describes the Rexx utility classes.

5.4.1. The DateTime Class

A DateTime object represents a point in between 1 January 0001 at 00:00.000000 and 31 December 9999 at 23:59:59.999999. A DateTime object has methods to allow formatting a date or time in various formats, as well as allowing arithmetic operations between dates.
Figure 5-28. The DateTime class and methods

<table>
<thead>
<tr>

**Note:** The DateTime class also has available class methods that its metaclass, the Class class, defines.
5.4.1.1. Inherited Methods

Methods inherited from the Object class.

- new (class method)
- \= \== \\== \< \>
- class
- copy
- defaultValue
- hasMethod
- identityHash
- init
- instanceMethod
- send
- instanceMethods
- sendWith
- isA
- setMethod
- objectName
- start
- objectName=
- string
- Request
- unMethodName
- Run

Methods inherited from the Comparable class.

- compareTo

Methods inherited from the Orderable class.

- \=<, \<=, \==, \<> , \>, <, =>, \<, <=, \>=, \<, <, >=, \<=, ">, >, <>

5.4.1.2. minDate (Class Method)

\>-minDate-------------------------------------------------------><

Returns a DateTime instance representing the minimum supported Rexx date, 1 January 0001 at 00:00:00.000000.

5.4.1.3. maxDate (Class Method)

\>-maxDate-------------------------------------------------------><

Returns a DateTime instance representing the maximum supported Rexx date, 31 December 9999 at 23:59:59.999999.

5.4.1.4. today (Class Method)

\>-today---------------------------------------------------------><

Returns a DateTime instance for the current day, with a time value of 00:00:00.000000.

5.4.1.5. fromNormalDate (Class Method)

\>-fromNormalDate(-date+----------------------------------+)-------------<

Creates a DateTime object from a string returned by the Normal option of the Date() built-in function. The time component will be set to the beginning of the input day (00:00:00.000000).
Chapter 5. The Builtin Classes

If specified, \textit{separator} identifies the field separator character used in the string. The separator must be a single character or the null string (\texttt{""}). A blank (\texttt{" "}) is the default separator.

If specified, \textit{offset} is the offset from UTC, in minutes. The \textit{offset} must be a valid whole number value. The default \textit{offset} is the current system offset timezone offset.

\subsection*{5.4.1.6. fromEuropeanDate (Class Method)}

\begin{verbatim}
>>-fromEuropeanDate(-date-+----------------------------+--)------------><
        +-,-+-----------+--+---------+
        +-separator-+ +-,offset-+
\end{verbatim}

Creates a \texttt{DateTime} object from a string returned by the European option of the \texttt{Date()} built-in function. The time component will be set to the beginning of the input day (00:00:00.000000).

If specified, \textit{separator} identifies the field separator character used in the string. The separator must be a single character or the null string (\texttt{""}). A slash (\texttt{"/"}) is the default separator. The time component will be set to the beginning of the input day (00:00:00.000000).

If specified, \textit{offset} is the offset from UTC, in minutes. The \textit{offset} must be a valid whole number value. The default \textit{offset} is the current system offset timezone offset.

\subsection*{5.4.1.7. fromOrderedDate (Class Method)}

\begin{verbatim}
>>-fromOrderedDate(-date-+----------------------------+--)------------><
        +-,-+-----------+--+---------+
        +-separator-+ +-,offset-+
\end{verbatim}

Creates a \texttt{DateTime} object from a string returned by the Ordered option of the \texttt{Date()} built-in function. The time component will be set to the beginning of the input day (00:00:00.000000).

If specified, \textit{separator} identifies the field separator character used in the string. The separator must be a single character or the null string (\texttt{""}). A slash (\texttt{"/"}) is the default separator. The time component will be set to the beginning of the input day (00:00:00.000000).

If specified, \textit{offset} is the offset from UTC, in minutes. The \textit{offset} must be a valid whole number value. The default \textit{offset} is the current system offset timezone offset.

\subsection*{5.4.1.8. fromStandardDate (Class Method)}

\begin{verbatim}
>>-fromStandardDate(-date-+----------------------------+--)------------><
        +-,-+-----------+--+---------+
        +-separator-+ +-,offset-+
\end{verbatim}

Creates a \texttt{DateTime} object from a string returned by the Standard option of the \texttt{Date()} built-in function. The time component will be set to the beginning of the input day (00:00:00.000000).

If specified, \textit{separator} identifies the field separator character used in the string. The separator must be a single character or the null string (\texttt{""}). A null string (\texttt{""}) is the default separator.
If specified, \texttt{offset} is the offset from UTC, in minutes. The \texttt{offset} must be a valid whole number value. The default \texttt{offset} is the current system offset timezone offset.

### 5.4.1.9. \texttt{fromUsaDate} (Class Method)

\begin{verbatim}
>>-fromUsaDate(-date-+----------------------------+--)------------><
     +-,-+-----------+--+---------+
     +-separator-+ +-,offset-+
\end{verbatim}

Creates a DateTime object from a string returned by the Usa option of the \texttt{Date()} built-in function. The time component will be set to the beginning of the input day (00:00:00.000000).

If specified, \texttt{separator} identifies the field separator character used in the string. The separator must be a single character or the null string (""). A slash (/) is the default separator.

If specified, \texttt{offset} is the offset from UTC, in minutes. The \texttt{offset} must be a valid whole number value. The default \texttt{offset} is the current system offset timezone offset.

### 5.4.1.10. \texttt{fromNormalTime} (Class Method)

\begin{verbatim}
>>-fromNormalTime(time--+---------+-)------------------------><
     +-,-offset-+
\end{verbatim}

Creates a DateTime object from a string returned by the Normal option of the \texttt{Time()} built-in function. The date component will be set to 1 January 0001.

If specified, \texttt{offset} is the offset from UTC, in minutes. The \texttt{offset} must be a valid whole number value. The default \texttt{offset} is the current system offset timezone offset.

### 5.4.1.11. \texttt{fromCivilTime} (Class Method)

\begin{verbatim}
>>-fromCivilTime(time--+---------+-)------------------------><
     +-,-offset-+
\end{verbatim}

Creates a DateTime object from a string returned by the Civil option of the \texttt{Time()} built-in function. The date component will be set to 1 January 0001.

If specified, \texttt{offset} is the offset from UTC, in minutes. The \texttt{offset} must be a valid whole number value. The default \texttt{offset} is the current system offset timezone offset.

### 5.4.1.12. \texttt{fromLongTime} (Class Method)

\begin{verbatim}
>>-fromLongTime(time--+---------+-)------------------------><
     +-,-offset-+
\end{verbatim}

Creates a DateTime object from a string returned by the Long option of the \texttt{Time()} built-in function. The date component will be set to 1 January 0001.
If specified, offset is the offset from UTC, in minutes. The offset must be valid whole number value. The default offset is the current system offset timezone offset.

5.4.1.13. fromBaseDate (Class Method)

```
>>-fromBaseDate(date--+---------+-)----------------------------<
  +-,offset+-
```

Creates a DateTime object from a string returned by the Basedate option of the Date() built-in function. The time component will be set to the beginning of the input day (00:00:00.000000).

If specified, offset is the offset from UTC, in minutes. The offset must be valid whole number value. The default offset is the current system offset timezone offset.

5.4.1.14. fromTicks (Class Method)

```
>>-fromTicks(time--+---------+-)------------------------><
  +-,offset+-
```

Creates a DateTime object from a string returned by the Ticks option of the Date() or Time() built-in functions.

If specified, offset is the offset from UTC, in minutes. The offset must be valid whole number value. The default offset is the current system offset timezone offset.

5.4.1.15. fromIsoDate (Class Method)

```
>>-fromIsoDate(date--+---------+-)------------------------><
  +-,offset+-
```

Creates a DateTime object from a string in ISO date format (yyyy-mm-ddThh:mm:ss.uuuuuu). The DateTime string method returns the ISO format as the string form of a DateTime object.

If specified, offset is the offset from UTC, in minutes. The offset must be valid whole number value. The default offset is the current system offset timezone offset.

5.4.1.16. fromUTCIsoDate (Class Method)

```
>>-fromUTCIsoDate(date)--------------------------------------><
```

Creates a DateTime object from a string in ISO timezone qualified date format (yyyy-mm-ddThh:mm:ss.uuuuuu+hhmm). The DateTime string method returns the ISO format as the string form of a DateTime object.
5.4.1.17. init

Initializes a new DateTime instance. If no arguments are specified, the DateTime instance is set to the current date and time. If the single fullDate argument is used, the DateTime argument is initialized to the date and time calculated by adding fullDate microseconds to 0001-01-01T00:00:00.000000. If the year, month, day, form is used, the DateTime instance is initialized to 00:00:00.000000 on the indicated date. Otherwise, the DateTime instance is initialized to the year, month, day, hours, minutes, seconds, and microseconds components. Each of these components must be a valid whole number within the acceptable range for the given component. For example, year must be in the range 1-9999, while minutes must be in the range 0-59.

If specified, offset is the offset from UTC, in minutes. The offset must be a valid whole number value. The default offset is the current system offset timezone offset.

Examples:

today = .DateTime~new -- initializes to current date and time
   -- initializes to 9 Sep 2007 at 00:00:00.000000
day = .DateTime~new(date('F', "20070930", "S"))
   -- also initializes to 9 Sep 2007 at 00:00:00.000000
day = .DateTime~new(2007, 9, 30)
   -- initializes to 9 Sep 2007 at 10:33:00.000000
day = .DateTime~new(2007, 9, 30, 10, 33, 00)

5.4.1.18. Arithmetic Methods

Note: For the prefix + operators, omit the parentheses and argument.

Returns the result of performing the specified arithmetic operation on the receiver DateTime object. Depending on the operation, the argument be either a TimeSpan object or a DateTime object. See the description of the individual operations for details. The arithmetic_operator can be:
Chapter 5. The Builtin Classes

+ Addition. Adds a TimeSpan to the DateTime object, returning a new DateTime instance. The receiver DateTime object is not changed. The TimeSpan may be either positive or negative.

- Subtraction. If argument is a DateTime object, the two times are subtracted, and a TimeSpan object representing the interval between the two times is returned. If the receiver DateTime is less than the argument argument DateTime, a negative TimeSpan interval is returned. The receiver DateTime object is not changed. If argument is a TimeSpan object, subtracts the TimeSpan from the DateTime object, returning a new DateTime instance. The receiver DateTime object is not changed. The TimeSpan may be either positive or negative.

Prefix - A prefix - operation on a DateTime object will raise a SYNTAX error condition.
Prefix + Returns a new instance of the DateTime object with the same time value.

Examples:

\[
t = \text{.dateTime\_new\_timeOfDay} \quad \text{return}\text{s TimeSpan for current time.}
\]

\[
say t \quad \text{dis\ysplays } "11:27:12.437000", \text{ perhaps}
\]

\[
d = \text{.dateTime\_new(2010, 4, 11)} \quad \text{creates new date}
\]

\[
future = d + t \quad \text{adds timespan to d}
\]

\[
say future \quad \text{dis\ysplays } "2010-04-11T11:27:12.437000" \quad \text{"real" start of next century}
\]

\[
nextCentury = \text{.dateTime\_new(2101, 1, 1)}
\]

\[
\text{dis\ysplays } "34060.12:25:49.922000", \text{ perhaps}
\]

\[
say "\text{The next century starts in" } (nextCentury - \text{.dateTime\_new})
\]

5.4.1.19. compareTo

\[
\text{compareTo(other)} \rightarrow
\]

This method returns "-1" if the other is larger than the receiving object, "0" if the two objects are equal, and "1" if other is smaller than the receiving object.

5.4.1.20. year

\[
\text{year} \rightarrow
\]

Returns the year represented by this DateTime instance.

5.4.1.21. month

\[
\text{month} \rightarrow
\]

Returns the month represented by this DateTime instance.
Chapter 5. The Builtin Classes

5.4.1.22. day

\texttt{\textasciitilde day}\langle

Returns the day represented by this \texttt{DateTime} instance.

5.4.1.23. hours

\texttt{\textasciitilde hours}\langle

Returns number of whole hours since midnight.

5.4.1.24. minutes

\texttt{\textasciitilde minutes}\langle

Returns minutes portion of the timestamp time-of-day.

5.4.1.25. seconds

\texttt{\textasciitilde seconds}\langle

Returns seconds portion of the timestamp time-of-day.

5.4.1.26. microseconds

\texttt{\textasciitilde microseconds}\langle

Returns microseconds portion of the timestamp time-of-day.

5.4.1.27. dayMinutes

\texttt{\textasciitilde dayMinutes}\langle

Returns the number of minutes since midnight in the time-of-day.

5.4.1.28. daySeconds

\texttt{\textasciitilde daySeconds}\langle

Returns the number of seconds since midnight in the time-of-day.
5.4.1.29. dayMicroseconds

>>-dayMicroseconds-------------------------------------------><

Returns the number of microseconds since midnight in the time-of-day.

5.4.1.30. hashCode

>>-hashCode---------------------------------------------------><

Returns a string value that is used as a hash value for a MapCollection such as Table, Relation, Set, Bag, and Directory.

5.4.1.31. addYears

>>-addYears(years)--------------------------------------------><

Add a number of years to the DateTime object, returning a new DateTime instance. The receiver DateTime object is unchanged. The years value must be a valid whole number. Negative values result in years being subtracted from the DateTime value.

The addYears method will take leap years into account. If the addition result would fall on February 29th of a non-leap year, the day will be rolled back to the 28th.

date = .DateTime~new(2008, 2, 29)
say date -- Displays "2008-02-29T00:00:00.000000"
say date~addYears(1) -- Displays "2009-02-29T00:00:00.000000"

5.4.1.32. addWeeks

>>-addWeeks(weeks)------------------------------------------><

Adds weeks to the DateTime object, returning a new DateTime instance. The receiver DateTime object is unchanged. The weeks value must be a valid number, including fractional values. Negative values result in week being subtracted from the DateTime value.

5.4.1.33. addDays

>>-addDays(days)--------------------------------------------><

Adds days to the DateTime object, returning a new DateTime instance. The receiver DateTime object is unchanged. The days value must be a valid number, including fractional values. Negative values result in days being subtracted from the DateTime value.

date = .DateTime~new(2008, 2, 29)
say date -- Displays "2008-02-29T00:00:00.000000"
say date~addDays(1.5) -- Displays "2008-03-01T12:00:00.000000"
5.4.1.34. addHours

```sql
>>-addHours(hours)------------------------------------------><
```

Adds hours to the DateTime object, returning a new DateTime instance. The receiver DateTime object is unchanged. The `hours` value must be a valid number, including fractional values. Negative values result in hours being subtracted from the DateTime value.

5.4.1.35. addMinutes

```sql
>>-addMinutes(minutes)--------------------------------------><
```

Adds minutes to the DateTime object, returning a new DateTime instance. The receiver DateTime object is unchanged. The `minutes` value must be a valid number, including fractional values. Negative values result in minutes being subtracted from the DateTime value.

5.4.1.36. addSeconds

```sql
>>-addSeconds(seconds)--------------------------------------><
```

Adds seconds to the DateTime object, returning a new DateTime instance. The receiver DateTime object is unchanged. The `seconds` value must be a valid number, including fractional values. Negative values result in seconds being subtracted from the DateTime value.

5.4.1.37. addMicroseconds

```sql
>>-addMicroseconds(microseconds)----------------------------><
```

Adds microseconds to the DateTime object, returning a new DateTime instance. The receiver DateTime object is unchanged. The `microseconds` value must be a valid whole number. Negative values result in microseconds being subtracted from the DateTime value.

5.4.1.38. isoDate

```sql
>>-isoDate--------------------------------------------------><
```

Returns a String formatted into ISO date format, `yyyy-dd-mmThh:mm:ss.uuuuuu`.

5.4.1.39. utcIsoDate

```sql
>>-utcIsoDate----------------------------------------------><
```

Returns a String formatted into a fully qualified ISO date format. If the timezone offset is 0, the format is `yyyy-dd-mmThh:mm:ss.uuuuuuZ`. If the offset is positive, the date is formatted as
yyyy-dd-mmThh:mm:ss.uuuuuu+hhmm. If the offset is negative, the result will be in the format
yyyy-dd-mmThh:mm:ss.uuuuuu-hhmm.

### 5.4.1.40. baseDate

>>>-baseDate--------------------------------------------------><

Returns the number of complete days (that is, not including the current day) since and including the base
date, 1 January 0001, in the format: **dddddd** (no leading zeros or whitespace characters).
The base date of 1 January 1970 is determined by extending the current Gregorian calendar backward
(365 days each year, with an extra day every year that is divisible by 4 except century years that are not
divisible by 400. It does not take into account any errors in the calendar system that created the
Gregorian calendar originally.

### 5.4.1.41. yearDay

>>>-yearDay--------------------------------------------------><

Returns the number of days, including the current day, that have passed in the DateTime year in the
format **ddd** (no leading zeros or blanks).

### 5.4.1.42. weekDay

>>>-weekDay--------------------------------------------------><

Returns the day of the week, as an integer. The values returned use the ISO convention for day
numbering. Monday is "1", Tuesday is "2", running through "7" for Sunday.

### 5.4.1.43. europeanDate

>>>-europeanDate(-+-----------+-)-------------------------------><
+--separator--+

Returns the date in the format **dd/mm/yy**. If specified, **separator** identifies the field separator character
used in the returned date. The separator must be a single character or the null string ("""). A slash ("/") is
the default separator.

### 5.4.1.44. languageDate

>>>-languageDate--------------------------------------------------><

Returns the date in an implementation- and language-dependent, or local, date format. The format is **dd
month yyyy**. The name of the month is according to the national language installed on the system. If no
local date format is available, the default format is returned.
5.4.1.45. monthName

Returns the name of the DateTime month, in English.

5.4.1.46. dayName

Returns the name of the DateTime day, in English.

5.4.1.47. normalDate

Returns the date in the format `dd mon yyyy`. If specified, `separator` identifies the field separator character used in the returned date. The separator must be a single character or the null string (""). A blank (" ") is the default separator.

5.4.1.48. orderedDate

Returns the date in the format `yy/mm/dd`. If specified, `separator` identifies the field separator character used in the returned date. The separator must be a single character or the null string (""). A slash ("/") is the default separator.

5.4.1.49. standardDate

Returns the date in the format `yyyymmdd`. If specified, `separator` identifies the field separator character used in the returned date. The separator must be a single character or the null string (""). A null string ("") is the default separator.
5.4.1.50. usaDate

>>>usaDate(+----------------------------->)---------------------------------->
     +-separator+-

Returns the date in the format mm/dd/yy. If specified, separator identifies the field separator character used in the returned date. The separator must be a single character or the null string (""). A slash ("/") is the default separator.

5.4.1.51. civilTime

>>>civilTime------------------------------------------------------------->

Returns the time in Civil format hh:mmxx. The hours can take the values 1 through 12, and the minutes the values 00 through 59. The minutes are followed immediately by the letters am or pm. This distinguishes times in the morning (12 midnight through 11:59 a.m.--appearing as 12:00am through 11:59am) from noon and afternoon (12 noon through 11:59 p.m.--appearing as 12:00pm through 11:59pm). The hour has no leading zero. The minute field shows the current minute (rather than the nearest minute) for consistency with other TIME results.

5.4.1.52. normalTime

>>>normalTime------------------------------------------------------------->

Returns the time in the default format hh:mm:ss. The hours can have the values 00 through 23, and minutes and seconds, 00 through 59. There are always two digits. Any fractions of seconds are ignored (times are never rounded). This is the default.

5.4.1.53. longTime

>>>longTime--------------------------------------------------------------->

Returns time in the format hh:mm:ss.uuuuuu (where uuuuuu are microseconds).

5.4.1.54. fullDate

>>>fullDate--------------------------------------------------------------->

Returns the number of microseconds since 00:00:00.000000 on 1 January 0001, in the format: ddddddddddddddddddd (no leading zeros or blanks).

5.4.1.55. utcDate

>>>utcDate--------------------------------------------------------------->
Chapter 5. The Builtin Classes

Returns the date converted to UTC time as the number of microseconds since 00:00:00.000000 on 1 January 0001, in the format: $ddddddddddddd$ (no leading zeros or blanks).

### 5.4.1.56. toTimeZone

```plaintext
>>-toTimeZone(+-+---+---+---+---+---+---+---+)
    +-offset+-
```

Returns a new DateTime object representing the time for the timezone indicated by `offset`. If specified, `offset` is the offset from UTC, in minutes. The `offset` must be a valid whole number value. The default `offset` 0, which creates a DateTime object for UTC.

### 5.4.1.57. ticks

```plaintext
>>-ticks-------------------------------------<
```

Returns the number of seconds since 00:00:00.000000 on 1 January 1970, in the format: $dddddddddddd$ (no leading zeros or blanks). Times prior to 1 January 1970 are returned as a negative value.

### 5.4.1.58. offset

```plaintext
>>-offset-------------------------------------<
```

Returns the timezone for the DateTime instance as the offset in minutes from UTC. Timezones east of UTC will return a positive offset. Timezones west of UTC will return a negative offset.

### 5.4.1.59. date

```plaintext
>>-date-------------------------------------<
```

Returns a new DateTime object instance for the current date, with the time component set to 00:00:00.000000.

### 5.4.1.60. timeOfDay

```plaintext
>>-timeOfDay-------------------------------------<
```

Returns the interval since 00:00:00.000000 of the current day as a TimeSpan object.

### 5.4.1.61. elapsed

```plaintext
>>-elapsed-------------------------------------<
```

Returns the difference between current time and the receiver Date\-Time as a Time\-Span object. The Time\-Span will be negative if the receiver Date\-Time represents a time in the future.

### 5.4.1.62. is\-Leap\-year

```oorexx
>>-is\-Leap\-year---------------------------------------------><
```

Returns true ("1") if the current year is leap year. Returns false ("0") if the current year is not a leap year.

### 5.4.1.63. days\-In\-Month

```oorexx
>>-days\-In\-Month--------------------------------------------><
```

Returns the number of days in the current month. For example, for dates in January, 31 is returned. The days\-In\-Month method takes leap years into account, returning 28 days for February in non\-leap years, and 29 days for leap years.

### 5.4.1.64. days\-In\-Year

```oorexx
>>-days\-In\-Year--------------------------------------------><
```

Returns the number of days in the current year. For leap years, 366 is returned. For non\-leap years, this returns 365.

### 5.4.1.65. string

```oorexx
>>-string-------------------------------------------------><
```

Returns DateTime formatted as a string. The string value is returned in ISO format.

### 5.4.2. The Alarm Class

An alarm object provides timing and notification capability by supplying a facility to send any message to any object at a given time. You can cancel an alarm before it sends its message.
Chapter 5. The Builtin Classes

Figure 5-29. The Alarm class and methods

Note: The Alarm class also has available class methods that its metaclass, the Class class, defines.

5.4.2.1. Inherited Methods

Methods inherited from the Object class.

- new (class method)
- isEqual\(\Rightarrow\) lessThan\(\Rightarrow\) greaterThan\(\Rightarrow\)
- class
- copy
- defaultName
- hasMethod
- identityHash
- init
- instanceMethod
- instanceMethods
- isA
- isInstanceOf
- methodName
- objectName
- objectName=
- Request
- Run
- send
- sendWith
- setMethod
- start
- string
- unsetMethod
- value

5.4.2.2. cancel

\[\text{>}>\text{-cancel}--------------------------------------------------\]

Cancels the pending alarm request represented by the receiver. This method takes no action if the specified time has already been reached.

5.4.2.3. init

\[\text{>}>\text{-init(atime, message)}-----------------------------------------\]

Sets up an alarm for a future time \textit{atime}. At this time, the alarm object sends the message that \textit{message}, a message object, specifies. (See The Message Class.) The \textit{atime} can a String, DateTime object, or TimeSpan object.

If \textit{atime} is a DateTime object, the DateTime specifies a time when the alarm will be triggered. The DateTime must be greater than the current time.
If `atime` is a `TimeSpan`, the Alarm will be set to the current time plus the `TimeSpan`. The `TimeSpan` must not be a negative interval.

If `atime` is a String, you can specify this as a date and time (`'hh:mm:ss'`) or as a number of seconds starting at the present time. If you use the date and time format, you can specify a date in the default format (`'dd Mmm yyyy'`) after the time with a single blank separating the time and date. Leading and trailing whitespace characters are not allowed in the `atime`. If you do not specify a date, the Alarm uses the first future occurrence of the specified time. You can use the `cancel()` method to cancel a pending alarm. See Initialization for more information.

### 5.4.2.4. Examples

The following code sets up an alarm at 5:10 p.m. on December 15, 2007. (Assume today's date/time is prior to December 15, 2007.)

```rexx
/* Alarm Examples */
PersonalMessage=.MyMessageClass~new("Call the Bank")
msg=.message~new(PersonalMessage,"RemindMe")

time = .DateTime~fromIsoDate("2007-12-15T17:10:00.000000")

a=.alarm~new(time, msg)
exit
::class MyMessageClass public
  ::method init
  expose inmsg
  use arg inmsg
  ::method RemindMe
  expose inmsg
  say "It is now " "TIME"("C")".Please "inmsg
/* On the specified date and time, displays the following message: */
/* "It is now 5:10pm. Please Call the Bank" */
```

For the following example, the user uses the same code as in the preceding example to define `msg`, a message object to run at the specified time. The following code sets up an alarm to run the `msg` message object in 30 seconds from the current time:

```rexx
a=.alarm~new(30,msg)
```

### 5.4.3. The TimeSpan Class

A `TimeSpan` object represents a point in between 1 January 0001 at 00:00:00.000000 and 31 December 9999 at 23:59:59.999999. A `TimeSpan` object has methods to allow formatting a date or time in various formats, as well as allowing arithmetic operations between dates.

Note: The TimeSpan class also has available class methods that its metaclass, the Class class, defines.

5.4.3.1. Inherited Methods

Methods inherited from the Object class.

new (class method) instanceMethod send
= <= == \== <> >> instanceMethods sendWith
Chapter 5. The Builtin Classes

Methods inherited from the Comparable class.

• compareTo

Methods inherited from the Orderable class.

=, !=, ==, <=, <, >, <=, >=, <=, >, <, ==, !=, <=, >, <=, <, ==, !=

5.4.3.2. fromDays (Class Method)

>>-fromDays(days)--------------------------------------------><

Creates a TimeSpan object from a number of days. The days argument must be a valid Rexx number.

5.4.3.3. fromHours (Class Method)

>>-fromHours(hours)------------------------------------------><

Creates a TimeSpan object from a number of hours. The hours argument must be a valid Rexx number.

5.4.3.4. fromMinutes (Class Method)

>>-fromMinutes(minutes)--------------------------------------><

Creates a TimeSpan object from a number of minutes. The minutes argument must be a valid Rexx number.

5.4.3.5. fromSeconds (Class Method)

>>-fromSeconds(seconds)--------------------------------------><

Creates a TimeSpan object from a number of seconds. The seconds argument must be a valid Rexx number.

5.4.3.6. fromMicroseconds (Class Method)

>>-fromMicroseconds(microseconds)---------------------------------><

Creates a TimeSpan object from a number of microseconds. The microseconds argument must be a valid Rexx number.
5.4.3.7. fromNormalTime (Class Method)

>>-fromNormalTime(time)---------------------------------------------><

Creates a TimeSpan object from a string returned by the Normal option of the Time() built-in function. The TimeSpan will contain an interval equal to the time of day represented by the string.

5.4.3.8. fromCivilTime (Class Method)

>>-fromCivilTime(time)----------------------------------------><

Creates a TimeSpan object from a string returned by the Civil option of the Time() built-in function. The TimeSpan will contain an interval equal to the time of day represented by the string.

5.4.3.9. fromLongTime (Class Method)

>>-fromLongTime(time)----------------------------------------><

Creates a TimeSpan object from a string returned by the Long option of the Time() built-in function. The TimeSpan will contain an interval equal to the time of day represented by the string.

5.4.3.10. fromStringFormat (Class Method)

>>-fromStringFormat(time)------------------------------------><

Creates a TimeSpan object from a string in the format returned by the TimeSpan string method.

5.4.3.11. init

>>-init(fullDate)---------------------------------------------><

>>-init(hours, minutes, seconds)-----------------------------><

>>-init(day, hours, minutes, second, microseconds)----------><

Initializes a new TimeSpan instance. If the single fullDate argument is used, the TimeSpan argument is initialized to the time span fullDate microseconds. Otherwise, the TimeSpan instance is initialized to either the hours, minutes, and seconds or the days, hours, minutes, seconds, and microseconds components. Each of these components must be a valid whole number within the acceptable range for the given component. For example, hours must be in the range 0-23, while minutes must be in the range 0-59.

Examples:

-- initializes to 15 hours, 37 minutes and 30 seconds
-- (15:37:30.000000)
span = .TimeSpan~new(time('F', "15:37:30", "N"))
-- also initializes to 15:37:30.000000
5.4.3.12. Arithmetic Methods

Note: For the prefix + operators, omit the parentheses and argument.

Returns the result of performing the specified arithmetic operation on the receiver TimeSpan object. Depending on the operation, the argument be either a TimeSpan object, a DateTime object, or a number. See the description of the individual operations for details. The arithmetic_operator can be:

+ Addition. If argument is a DateTime object, the TimeSpan is added to the DateTime object, returning a new DateTime instance. Neither the receiver TimeSpan or the argument DateTime object is altered by this operation. The TimeSpan may be either positive or negative.
   If argument is a TimeSpan object, the two TimeSpans are added together, and a new TimeSpan instance is returned. Neither the TimeSpan object is altered by this operation.

- Subtraction. The argument must be a TimeSpan object. The argument TimeSpan is subtracted from the receiver TimeSpan and a new TimeSpan instance is returned. Neither the TimeSpan object is altered by this operation.

* Multiplication. The argument must be a valid Rexx number. The TimeSpan is multiplied by the argument value, and a new TimeSpan instance is returned. The receiver TimeSpan object is not altered by this operation.

/ Division. The argument must be a valid Rexx number. The TimeSpan is divided by the argument value, and a new TimeSpan instance is returned. The receiver TimeSpan object is not altered by this operation. The / operator and % produce the same result.

% Integer Division. The argument must be a valid Rexx number. The TimeSpan is divided by the argument value, and a new TimeSpan instance is returned. The receiver TimeSpan object is not altered by this operation. The / operator and % produce the same result.

// Remainder Division. The argument must be a valid Rexx number. The TimeSpan is divided by the argument value and the division remainder is returned as a new TimeSpan instance. The receiver TimeSpan object is not altered by this operation.

Prefix - The TimeSpan is negated, returning a new TimeSpan instance. The receiver TimeSpan is not altered by this operation.

Prefix + Returns a new instance of the TimeSpan object with the same time value.

Examples:
Chapter 5. The Builtin Classes

t1 = .timespan~fromHours(1)
t2 = t1 * 2
-- displays "01:00:00.000000 01:30:00.000000 02:30:00.000000"
say t1 t2 (t1 + t2)

5.4.3.13. compareTo

>>>compareTo(other)--------------------------------------------------------><
This method returns "-1" if the other is larger than the receiving object, "0" if the two objects are equal, and "1" if other is smaller than the receiving object.

5.4.3.14. duration

>>>duration--------------------------------------------------------><
Returns a new TimeSpan object containing the absolute value of the receiver TimeSpan object.

5.4.3.15. days

>>>days--------------------------------------------------------><
Returns the number of whole days in the TimeSpan, as a positive number.

5.4.3.16. hours

>>>hours--------------------------------------------------------><
Returns the hours component of the TimeSpan, as a positive number.

5.4.3.17. minutes

>>>minutes--------------------------------------------------------><
Returns the minutes component of the TimeSpan, as a positive number.

5.4.3.18. seconds

>>>seconds--------------------------------------------------------><
Returns the seconds component of the TimeSpan, as a positive number.
5.4.3.19. microseconds

>>>-microseconds----------------------------------------------><

Returns the microseconds component of the TimeSpan, as a positive number.

5.4.3.20. totalDays

>>>-totalDays------------------------------------------------------><

Returns the time span expressed as a number of days. The result includes any fractional part and retains
the sign of the receiver TimeSpan.

5.4.3.21. totalHours

>>>-totalHours------------------------------------------------------><

Returns the time span expressed as a number of hours. The result includes any fractional part and retains
the sign of the receiver TimeSpan.

5.4.3.22. totalMinutes

>>>-totalMinutes------------------------------------------------------><

Returns the time span expressed as a number of minutes. The result includes any fractional part and retains
the sign of the receiver TimeSpan.

5.4.3.23. totalSeconds

>>>-totalSeconds------------------------------------------------------><

Returns the time span expressed as a number of seconds. The result includes any fractional part and retains
the sign of the receiver TimeSpan.

5.4.3.24. totalMicroseconds

>>>-totalMicroseconds----------------------------------------------><

Returns the time span expressed as a number of microseconds. The result retains the sign of the receiver
TimeSpan.

5.4.3.25. hashCode

>>>-hashCode--------------------------------------------------><
Chapter 5. The Builtin Classes

Returns a string value that is used as a hash value for MapCollection such as Table, Relation, Set, Bag, and Directory.

5.4.3.26. addWeeks

```>>>-addWeeks(weeks)--------------------------------------------><```

Adds weeks to the TimeSpan object, returning a new TimeSpan instance. The receiver TimeSpan object is unchanged. The `weeks` value must be a valid number, including fractional values. Negative values result in week being subtracted from the TimeSpan value.

5.4.3.27. addDays

```>>>-addDays(days)--------------------------------------------><```

Adds days to the TimeSpan object, returning a new TimeSpan instance. The receiver TimeSpan object is unchanged. The `days` value must be a valid number, including fractional values. Negative values result in days being subtracted from the TimeSpan value.

5.4.3.28. addHours

```>>>-addHours(hours)--------------------------------------------><```

Adds hours to the TimeSpan object, returning a new TimeSpan instance. The receiver TimeSpan object is unchanged. The `hours` value must be a valid number, including fractional values. Negative values result in hours being subtracted from the TimeSpan value.

5.4.3.29. addMinutes

```>>>-addMinutes(minutes)------------------------------------------><```

Adds minutes to the TimeSpan object, returning a new TimeSpan instance. The receiver TimeSpan object is unchanged. The `minutes` value must be a valid number, including fractional values. Negative values result in minutes being subtracted from the TimeSpan value.

5.4.3.30. addSeconds

```>>>-addSeconds(seconds)------------------------------------------><```

Adds seconds to the TimeSpan object, returning a new TimeSpan instance. The receiver TimeSpan object is unchanged. The `seconds` value must be a valid number, including fractional values. Negative values result in seconds being subtracted from the TimeSpan value.
5.4.3.31. addMicroseconds

```ooRexx
>>-addMicroseconds(microseconds)----------------------------><
```

Adds microseconds to the TimeSpan object, returning a new TimeSpan instance. The receiver TimeSpan object is unchanged. The `microseconds` value must be a valid whole number. Negative values result in microseconds being subtracted from the TimeSpan value.

5.4.3.32. sign

```ooRexx
>>-sign-----------------------------------------------------><
```

Returns "-1" if the TimeSpan is negative, "1" if the TimeSpan is positive, and "0" if the TimeSpan duration is zero.

5.4.3.33. string

```ooRexx
>>-string-------------------------------------------------><
```

Returns TimeSpan formatted as a string. The string value is in the format "-dddddddd.hh:mm:ss.uuuuuu". If the TimeSpan is positive or zero, the sign is omitted. The days field will be formatted without leading zeros or blanks. If the TimeSpan duration is less than a day, the days field and the period separator will be omitted.

5.4.4. The Comparable Class

This class is defined as a mixin class.

Figure 5-31. The Comparable class and methods

```
| Object |

| Comparable |

| compareTo |
```

**Note:** The Comparable class also has available class methods that its metaclass, the `Class class`, defines.
5.4.4.1. Inherited Methods

Methods inherited from the Object class.

new (class method) instanceMethod send
\= \== \\=< \=> \\
instanceMethods sendWith
class isEqual isA setMethod
copy isInstanceOf start
defaultName objectName startWith
hasMethod objectName= string
identityHash Request unsetMethod
init Run

5.4.4.2. compareTo

This method compares the receiving object to the object supplied in the comparable argument.

>>-compareTo(other)---------------------------------------><

This method returns "-1" if the other is larger than the receiving object, "0" if the two objects are equal, and "1" if other is smaller than the receiving object.

5.4.5. The Orderable Class

The Orderable class can be inherited by classes which wish to provide each of the comparison operator methods without needing to implement each of the individual methods. The inheriting class need only implement the Comparable compareTo() method. See This class is defined as a mixin class.

Figure 5-32. The Orderable class and methods

<table>

| \<< \=>> |

316 ooRexx Reference Version 4.0.0
5.4.5.1. Inherited Methods

Methods inherited from the Object class.

new (class method) instanceMethod send
\= \<= \!== <\> \\
instanceMethods sendWith
\class isA setMethod
\copy isInstanceOf start
\defaultName objectName startWith
\hasMethod objectName= string
\identityHash Request unsetMethod
\init Run

5.4.5.2. Comparison Methods

>>>-comparison_operator(argument)-----------------------------------><

Returns 1 (true) or 0 (false), the result of performing the specified comparison operation. The receiver object and the argument are the terms compared.

The comparison operators you can use in a message are:

\= True if the terms are equal
\\=, >\<, <\> True if the terms are not equal (inverse of \=)
\> Greater than
\< Less than
\>= Greater than or equal to
\\< Not less than
\<= Less than or equal to
\\> Not greater than

All strict comparison operations have one of the characters doubled that define the operator. The Orderable strict comparison operators produce the same results as the non-strict comparisons.

The strict comparison operators you can use in a message are:

== True if terms are strictly equal
\\== True if the terms are NOT strictly equal (inverse of ==)
\>> Strictly greater than
\<< Strictly less than
\\>> Strictly greater than or equal to
\\<< Strictly NOT less than
\<<= Strictly less than or equal to
\\<<= Strictly NOT greater than
5.4.6. The Comparator Class

The Comparator class is the base class for implementing Comparator objects that can be used with the Array sortWith() or stableSortWith() method. The compare() method implements some form of comparison that determines the relative ordering of two objects. Many Comparator implementations are specific to particular object types.

Figure 5-33. The Comparator class and methods

```
<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comparator</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>compare</td>
</tr>
</tbody>
</table>
```

Note: The Comparator class also has available class methods that its metaclass, the Class class, defines.

This class is defined as a mixin class.

5.4.6.1. Inherited Methods

Methods inherited from the Object class.

```
new (class method)  instanceMethod  send
= \== \== <= <> ><
class               instanceMethods  sendWith
copy                isaA             setMethod
defaultName         isInstanceOf    start
hasMethod           objectName      startWith
identityHash        objectName=     string
init                Request          unsetMethod
                  Run              
```

5.4.6.2. compare

```
>>-compare(first, second)--------------------------------><
```

This method returns "-1" if the second is larger than first object, "0" if the two objects are equal, and "1" second is smaller than first.

The default Comparator compare() method assumes that first is an object that implements the Comparable compareTo() method. Subclasses may override this to implement more specific comparisons.
5.4.7. The CaselessComparator Class

The CaselessComparator class performs caseless orderings of String objects.

Figure 5-34. The CaselessComparator class and methods

![Diagram showing the inheritance hierarchy of the CaselessComparator class]

Note: The CaselessComparator class also has available class methods that its metaclass, the Class class, defines.

This class is defined as a mixin class.

5.4.7.1. Inherited Methods

Methods inherited from the Object class.

- `new` (class method)
- `=` `==` `===` `<` `>` `>`
- `class`
- `copy`
- `defaultName`
- `hasMethod`
- `identityHash`
- `init`
- `instanceMethod`
- `instanceMethods`
- `isA`
- `isInstanceOf`
- `objectName`
- `objectName=`
- `Request`
- `Run`
- `send`
- `sendWith`
- `setMethod`
- `start`
- `string`
- `unsetMethod`

Methods inherited from the Comparator class.

- `compare`

5.4.7.2. compare

`>>>compare(first,second)<`-------------------->

This method returns "-1" if the second is larger than first object, "0" if the two objects are equal, and "1" second is smaller than first. The two strings are compared using a caseless comparison.
Chapter 5. The Builtin Classes

5.4.8. The ColumnComparator Class

The CaselessColumnComparator class performs orderings based on specific substrings of String objects.

Figure 5-35. The ColumnComparator class and methods

Note: The ColumnComparator class also has available class methods that its metaclass, the Class class, defines.

This class is defined as a mixin class.

5.4.8.1. Inherited Methods

Methods inherited from the Object class.

new (class method) instanceMethod send
= \== \== < <> class instanceMethods sendWith
\== <= => copy isA setMethod
defaultName isInstanceOf start
hasMethod objectName startWith
identityHash objectName= string
init Request unsetMethod
Run

Methods inherited from the Comparator class.

compare

5.4.8.2. compare

>>>-compare(first,second)-----------------------------<

This method returns "-1" if the second is larger than first object, "0" if the two objects are equal, and "1" second is smaller than first. Only the defined columns of the strings are compared.
5.4.8.3. init

>>>init(start, length)----------------------------------><

Initializes a comparator to sort strings starting at position start for length characters.

5.4.9. The CaselessColumnComparator Class

The CaselessColumnComparator class performs caseless orderings of specific substrings of String objects.

Figure 5-36. The CaselessColumnComparator class and methods

This class is defined as a mixin class.

5.4.9.1. Inherited Methods

Methods inherited from the Object class.

new (class method)  instanceMethod  send
= '%  '==' '<><'
class           instanceMethods  sendWith
copy            isA             setMethod
defaultName     isInstanceOf    start
hasMethod       objectName      startWith
identityHash    objectName=     string
init            Request         unsetMethod
                Run

Methods inherited from the Comparator class.
5.4.9.2. compare

```plaintext
>>-compare(first,second)---------------------------------->
```

This method returns "-1" if the `second` is larger than `first` object, "0" if the two objects are equal, and "1" if `second` is smaller than `first`. Only the defined columns of the strings are compared, using a caseless comparison.

5.4.9.3. init

```plaintext
>>-init(start, length)---------------------------------->
```

Initializes a comparator to sort strings starting at position `start` for `length` characters.

5.4.10. The DescendingComparator Class

The DescendingComparator class performs sort orderings in descending order. This is the inverse of a Comparator sort order.

This class is defined as a mixin class. It must be used by inheriting from it as a mixin.

Figure 5-37. The DescendingComparator class and methods

```
Object

Comparator

DescendingComparator

compare
```

**Note:** The DescendingComparator class also has available class methods that its metaclass, the Class class, defines.

This class is defined as a mixin class.
5.4.10.1. Inherited Methods

Methods inherited from the Object class.

- new (class method)
- instanceMethod send
- <= <= <> >=
- isA instanceMethods sendWith
- copy isInstanceOf start
- defaultName objectName startWith
- hasMethod objectName= string
- identityHash Request unsetMethod
- init Run

Methods inherited from the Comparator class.

compare

5.4.10.2. compare

>>-compare(first,second)--------------------------------><

This method returns "1" if the second is larger than first object, "0" if the two objects are equal, and "-1" second is smaller than first, resulting in a descending sort sequence. The DescendingComparator assumes the first object implements the Comparable compareTo() method.

5.4.11. The CaselessDescendingComparator Class

The CaselessDescendingComparator class performs caseless string sort orderings in descending order. This is the inverse of a CaselessComparator sort order.
Figure 5-38. The CaselessDescendingComparator class and methods
Note: The CaselessDescendingComparator class also has available class methods that its metaclass, the Class class, defines.

This class is defined as a mixin class.

5.4.11.1. Inherited Methods

Methods inherited from the Object class.

Methods inherited from the Comparator class.

5.4.11.2. compare

```>
>>-compare(first,second)--------------------------------><
```

This method returns "1" if the second is larger than first object, "0" if the two objects are equal, and "-1" second is smaller than first. The two strings are compared using a caseless comparison.

5.4.12. The InvertingComparator Class

The InvertingComparator class inverts the comparison results of another Comparator object to reverse the resulting sort order.
This class is defined as a mixin class.

5.4.12.1. Inherited Methods

Methods inherited from the Object class.

| new (class method) | instanceMethod | send |
| class             | instanceMethods| sendWith |
| copy              | isa            | setMethod |
| defaultName       | isInstanceOf   | start |
| hasMethod         | objectName     | startWith |
| identityHash      | Request        | unsetMethod |
| init              | Run            |        |

Methods inherited from the Comparator class.

| compare            |

5.4.12.2. compare

>>>-compare(first,second)--------------------------><

This method returns "1" if the second is larger than first object, "0" if the two objects are equal, and "-1" second is smaller than first, resulting in a descending sort sequence. The InvertingComparator will invert the ordering returned by the provided Comparator.
5.4.12.3. **init**

```init(comparator)```

Initializes an inverting comparator to sort strings using an inversion of the result from the `comparator` compare() method.

5.4.13. **The Monitor Class**

The Monitor class acts as a proxy for other objects. Messages sent to the Monitor object are forwarded to a different target object. The message target can be changed dynamically.

![Figure 5-40. The Monitor class and methods](image)

*Note:* The Monitor class also has available class methods that its metaclass, the `Class` class, defines.

5.4.13.1. **Inherited Methods**

Methods inherited from the `Object` class.

- `new (class method)`
- `<=` `==` `<` `>` `<<`
- `class`
- `copy`
- `defaultName`
- `hasMethod`
- `identityHash`
- `init`
- `instanceMethod`
- `instanceMethods`
- `isA`
- `isEqual`
- `objectName`
- `objectName=`
- `Request`
- `Run`
- `send`
- `sendWith`
- `start`
- `startWith`
- `string`
- `unsetMethod`
Chapter 5. The Builtin Classes

5.4.13.2. current

```plaintext
>>-current-----------------------------------------------<
```

Returns the current destination object.

5.4.13.3. destination

```plaintext
>>-destination+-+------------------+--------------------------------><
+(destination)+
```

Returns a new destination object. If you specify `destination`, this becomes the new destination for any forwarded messages. If you omit `destination`, the previous destination object becomes the new destination for any forwarded messages.

5.4.13.4. init

```plaintext
>>-init+-+------------------+-------------------------------------><
+(destination)+
```

Initializes the newly created monitor object.

5.4.13.5. unknown

```plaintext
>>-unknown(messagename,messageargs)-----------------------><
```

Reissues or forwards to the current monitor destination all unknown messages sent to a monitor object. For additional information, see Defining an unknown Method.

5.4.13.6. Examples

```plaintext
.local~setentry("output",.monitor~new(.stream~new("my.new")~~command("open nobuffer")))

/* The following sets the destination */
previous_destination=.output~destination(.stream~new("my.out")~~command("open write"))
/* The following resets the destination */
.output~destination

.output~destination(.Stdout)
current_output_destination_stream_object=.output~current
```

5.4.14. The MutableBuffer Class

The MutableBuffer class is a buffer on which certain string operations such as concatenation can be performed very efficiently. Unlike String objects, MutableBuffers can be altered without requiring a new
object allocation. A MutableBuffer object can provide better performance for algorithms that involve frequent concatenations to build up longer string objects because it creates fewer intermediate objects.

**Figure 5-41. The MutableBuffer class and methods**

```plaintext
Object

MutableBuffer

**Note:** The MutableBuffer class also has available class methods that its metaclass, the Class class, defines.
Chapter 5. The Builtin Classes

5.4.14.1. Inherited Methods

Methods inherited from the Object class.

- `new` (class method)
- `=`
- `\` = `\`
- `<<` (class method)
- `>>`
- `instanceMethod`
- `instanceMethods`
- `send`
- `sendWith`
- `isA`
- `isInstanceOf`
- `start`
- `copy`
- `startWith`
- `defaultName`
- `objectName`
- `objectName=" "`
- `hasMethod`
- `string`
- `identityHash`
- `Request`
- `Run`
- `Request`
- `unsetMethod`

5.4.14.2. new

```rexx
>>-new(-+--------+-+---------------+-)--------------------><
+-string+ --,-,buffersize++
```

Initialize the buffer, optionally assign a buffer content and a starting `buffer size`. The default size is 256; the buffer size increases to the length of `string` if the string does not fit into the buffer.

5.4.14.3. append

```rexx
>>-append(string)------------------------------------------><
```

Appends `string` to the buffer content. The buffer size is increased if necessary.

5.4.14.4. caselessChangeStr

```rexx
>>-caselessChangeStr(needle,newneedle--+-+----)-----------------------------------><
+-,count+-
```

Returns the receiver `MutableBuffer` `newneedle` replacing occurrences of `needle`. If `count` is not specified, all occurrences of `needle` are replaced. If `count` is specified, it must be a positive, whole number that gives the maximum number of occurrences to be replaced. The `needle` searches are performed using caseless comparisons.

5.4.14.5. caselessCountStr

```rexx
>>-caselessCountStr(needle)--------------------------------------------><
```

Returns a count of the occurrences of `needle` in the receiving `MutableBuffer` that do not overlap. All matches are made using caseless comparisons.

5.4.14.6. caselessLastPos

```rexx
>>-caselessLastPos(needle--+-+----)--------------------------><
```

Returns the last position of `needle` in the receiving `MutableBuffer` that does not overlap. All matches are made using caseless comparisons.
Chapter 5. The Builtin Classes

Returns the position of the last occurrence of a string, needle, in the receiving buffer. (See also POS.) It returns 0 if needle is the null string or not found. By default, the search starts at the last character of the receiving buffer and scans backward to the beginning of the string. You can override this by specifying start, the point at which the backward scan starts and length, the range of characters to scan. The start must be a positive whole number and defaults to receiving_buffer~length if larger than that value or omitted. The length must be a non-negative whole number and defaults to start. The search is performed using caseless comparisons.

5.4.14.7. caselessMatch

>>>caselessMatch(start,other)------------------------------------------><
   ++,-,-----------------+-+-------+--+---------+-+
   +-n-+    +-,length-+

Returns .true ("1") if the characters of the other match the characters of the target buffer beginning at position start. Return .false ("0") if the characters are not a match. The matching is performed using caseless comparisons. start must be a positive whole number less than or equal to the length of the target buffer.

If n is specified, the match will be performed starting with character n of other. The default value for n is "1". n must be a positive whole number less than or equal to the length of other.

If length is specified, it defines a substring of other that is used for the match. length must be a positive whole number and the combination of n and length must be a valid substring within the bounds of other.

The caselessMatch method is useful for efficient string parsing as it does not require new string objects be extracted from the target string.

5.4.14.8. caselessMatchChar

>>>caselessMatchChar(n,chars)----------------------------------------><

Returns .true ("1") if the character at position n matches any character of the string chars. Returns .false ("0") if the character does not match any of the characters in the reference set. The match is made using caseless comparisons. The argument n must be a positive whole number less than or equal to the length of the target MutableBuffer.

5.4.14.9. caselessPos

>>>caselessPos(needle)-----------------------------------------------><
   ++,-,-----------------+-+-------+--+---------+-+
   +-,length-+

Returns the position in the receiving buffer of a needle string. (See also caselessLastPos.) It returns 0 if needle is the null string or is not found or if start is greater than the length of the receiving buffer. The search is performed using caseless comparisons. By default, the search starts at the first character of the
receiving buffer (that is, the value of \texttt{start} is 1), and continues to the end of the buffer. You can override this by specifying \texttt{start}, the point at which the search starts, and \texttt{length}, the bounding limit for the search. If specified, \texttt{start} must be a positive whole number and \texttt{length} must be a non-negative whole number.

### 5.4.14.10. \texttt{caselessWordPos}

\begin{verbatim}
>>-caselessWordPos(phrase-+--------+-)---------------------------------><
 ++,start++
\end{verbatim}

Returns the word number of the first word of \texttt{phrase} found in the receiving buffer, or 0 if \texttt{phrase} contains no words or if \texttt{phrase} is not found. Word matches are made independent of case. Multiple whitespace characters between words in either \texttt{phrase} or the receiving buffer are treated as a single blank for the comparison, but, otherwise, the words must match exactly.

By default the search starts at the first word in the receiving string. You can override this by specifying \texttt{start} (which must be positive), the word at which the search is to be started.

### 5.4.14.11. \texttt{changeStr}

\begin{verbatim}
>>-changeStr(needle,newneedle--+--------+--)---------------------------------><
 +-,count+-
\end{verbatim}

Returns the receiver \texttt{MutableBuffer} with \texttt{newneedle} replacing occurrences of \texttt{needle}.

If \texttt{count} is not specified, all occurrences of \texttt{needle} are replaced. If \texttt{count} is specified, it must be a positive, whole number that gives the maximum number of occurrences to be replaced.

### 5.4.14.12. \texttt{countStr}

\begin{verbatim}
>>-countStr(needle)--------------------------------------------><
\end{verbatim}

Returns a count of the occurrences of \texttt{needle} in the receiving buffer that do not overlap.

### 5.4.14.13. \texttt{delete}

\begin{verbatim}
>>-delete(n-+---------+--)-------------------------------><
 +-,length+-
\end{verbatim}

Deletes \texttt{length} characters from the buffer beginning at the \texttt{n}'th character. If \texttt{length} is omitted, or if \texttt{length} is greater than the number of characters from \texttt{n} to the end of the buffer, the method deletes the remaining buffer contents (including the \texttt{n}'th character). The length must be a positive integer or zero. The \texttt{n} must be a positive integer. If \texttt{n} is greater than the length of the buffer or zero, the method does not modify the buffer content.
5.4.14.14. delstr

\>
\>

Deletes length characters from the buffer beginning at the \( n \)'th character. If length is omitted, or if length is greater than the number of characters from \( n \) to the end of the buffer, the method deletes the remaining buffer contents (including the \( n \)'th character). The length must be a positive integer or zero. The \( n \) must be a positive integer. If \( n \) is greater than the length of the buffer or zero, the method does not modify the buffer content. The delstr() method is the same as the delete() method. It is provided for polymorphism with the String class.

5.4.14.15. delWord

\>
\>

Deletes a substring from the MutableBuffer the substring that starts at the \( n \)th word and is of length whitespace-delimited words. If you omit length, or if length is greater than the number of words from \( n \) to the end of the receiving buffer, the method deletes the remaining words in the receiving buffer (including the \( n \)th word). The length must be a positive whole number or zero. The \( n \) must be a positive whole number. If \( n \) is greater than the number of words in the receiving buffer, the method returns the receiving buffer unchanged. The portion deleted includes any whitespace characters following the final word involved but none of the whitespace characters preceding the first word involved.

5.4.14.16. getBufferSize

\>
\>

Retrieves the current buffer size.

5.4.14.17. insert

\>
\>

Inserts the string new, padded or truncated to length length, into the mutable buffer after the \( n \)'th character. The default value for \( n \) is 0, which means insertion at the beginning of the string. If specified, \( n \) and length must be positive integers or zeros. If \( n \) is greater than the length of the buffer contents, the string new is padded at the beginning. The default value for length is the length of new. If length is less than the length of string new, insert truncates new to length length. The default pad character is a blank.
Chapter 5. The Builtin Classes

5.4.14.18. lastPos

\[ \text{lastPos}(\text{needle}) \]

Returns the position of the last occurrence of a string, \texttt{needle}, in the receiving buffer. (See also \texttt{POS}.) It returns 0 if \texttt{needle} is the null string or not found. By default, the search starts at the last character of the receiving buffer and scans backward. You can override this by specifying \texttt{start}, the point at which the backward scan starts. The \texttt{start} must be a positive whole number and defaults to \texttt{receiving_buffer~length} if larger than that value or omitted.

Examples:

\begin{verbatim}
x1 = .mutablebuffer~new("abc def ghi")
x1~lastPos(" ") -> 8
x1 = .mutablebuffer~new("abcdefghi")
x1~lastPos(" ") -> 0
x1 = .mutablebuffer~new("efgxyz")
x1~lastPos("xy") -> 4
x1 = .mutablebuffer~new("abc def ghi")
x1~lastPos(" ",7) -> 4
\end{verbatim}

5.4.14.19. length

\[ \text{length} \]

Returns length of data in buffer.

5.4.14.20. lower

\[ \text{lower}(n, length) \]

Returns the receiving buffer with the characters of the target string beginning with character \texttt{n} for \texttt{length} characters converted to lowercase. If \texttt{n} is specified, it must be a positive whole number. If \texttt{n} is not specified, the case conversion will start with the first character. If \texttt{length} is specified, it must be a non-negative whole number. If \texttt{length} the default is to convert the remainder of the buffer.

5.4.14.21. makeArray

\[ \text{makeArray}(Separator) \]

This method returns an array of strings containing the substrings that were separated using the separator character. The default separator is the newline character.
5.4.14.22. match

\[ \text{match}(\text{start}, \text{other}) \]

Returns .true ("1") if the characters of the other match the characters of the target buffer beginning at position start. Return .false ("0") if the characters are not a match. start must be a positive whole number less than or equal to the length of the target buffer.

If n is specified, the match will be performed starting with character n of other. The default value for n is "1". n must be a positive whole number less than or equal to the length of other.

If length is specified, it defines a substring of other that is used for the match. length must be a positive whole number and the combination of n and length must be a valid substring within the bounds of other.

The match method is useful for efficient string parsing as it does not require new string objects be extracted from the target buffer.

5.4.14.23. matchChar

\[ \text{matchChar}(\text{n}, \text{chars}) \]

Returns .true ("1") if the character at position n matches any character of the string chars. Returns .false ("0") if the character does not match any of the characters in the reference set. The argument n must be a positive whole number less than or equal to the length of the target buffer.

5.4.14.24. overlay

\[ \text{overlay}(\text{new}, \text{length}, \text{pad}) \]

Modifies the buffer content by overlaying it, starting at the n’th character, with the string new, padded or truncated to length length. The overlay can extend beyond the end of the buffer. In this case the buffer size will be increased. If you specify length, it must be a positive integer or zero. The default value for length is the length of new. If n is greater than the length of the buffer content, padding is added before the new string. The default pad character is a blank, and the default value for n is 1. If you specify n, it must be a positive integer.

5.4.14.25. pos

\[ \text{pos}(\text{needle}, \text{start}) \]

Returns the position in the receiving buffer of another string, needle. (See also lastPos.) It returns 0 if needle is the null string or is not found or if start is greater than the length of the receiving buffer. By default, the search starts at the first character of the receiving buffer (that is, the value of start is 1). You
can override this by specifying start (which must be a positive whole number), the point at which the search starts.

Examples:

```rxml
x1 = .mutablebuffer~new("Saturday")
x1~pos("day")          -> 6
x1 = .mutablebuffer~new("abc def ghi")
x1~pos("x")            -> 0
x1~pos(" ")            -> 4
x1~pos(" ",5)          -> 8
```

5.4.14.26. replaceAt

```rxml
replaceAt(new,n,length+----+-)----->
+-+,pad+-
```

Returns the receiving buffer with the characters from the n'th character for length characters replaced with new. The replacement position and length can extend beyond the end of the receiving string. The starting position, n, must be a positive whole number, and the length must be a positive whole number or zero. If n is greater than the length of the receiving string, padding is added before the new string. The default pad character is a blank.

5.4.14.27. setBufferSize

```rxml
setBufferSize(n)------------------------>
```

Sets the buffer size. If n is less than the length of buffer content, the content is truncated. If n is 0, the entire contents is erased and the new buffer size is the value given in the init method.

5.4.14.28. string

```rxml
string----------------------------->
```

Retrieves the content of the buffer as a string.

5.4.14.29. subchar

```rxml
subchar(n)------------------------>
```

Returns the n'th character of the receiving buffer. n must be a positive whole number. If n is greater that the length of the receiving buffer then a zero-length string is returned.
5.4.14.30. substr

Returns a substring from the buffer content that begins at the n’th character and is of length length, padded with pad if necessary. The n must be a positive integer. If n is greater than receiving_string-length, only pad characters are returned. If you omit length, the remaining buffer content is returned. The default pad character is a blank.

5.4.14.31. subWord

Returns the substring of the receiving buffer that starts at the nth word and is up to length whitespace-delimited words. The n must be a positive whole number. If you omit length, it defaults to the number of remaining words in the receiving buffer. The returned string never has leading or trailing whitespace characters, but includes all whitespace characters between the selected words.

5.4.14.32. translate

Returns the receiving buffer with each character translated to another character or unchanged. The output table is tableo and the input translation table is tablei. translate searches tablei for each character in the receiving buffer. If the character is found, the corresponding character in tableo is replaces the character in the buffer. If there are duplicates in tablei, the first (leftmost) occurrence is used. If the character is not found, the original character in the receiving buffer is unchanged. The tables can be of any length. If you specify neither translation table and omit pad, the receiving string is translated to uppercase (that is, lowercase a-z to uppercase A-Z), but if you include pad the buffer translates the entire string to pad characters. tablei defaults to XRANGE("00"x,"FF"x), and tableo defaults to the null string and is padded with pad or truncated as necessary. The default pad is a blank.

n is the position of the first character of the translated range. The default starting position is 1. length is the range of characters to be translated. If omitted, length remainder of the buffer from the starting position to the end is used.

5.4.14.33. upper

Returns the receiving buffer with each character translated to uppercase (that is, lowercase a-z to uppercase A-Z), but if you include pad the buffer translates the entire string to pad characters. tablei defaults to XRANGE("00"x,"FF"x), and tableo defaults to the null string and is padded with pad or truncated as necessary. The default pad is a blank.

n is the position of the first character of the translated range. The default starting position is 1. length is the range of characters to be translated. If omitted, length remainder of the buffer from the starting position to the end is used.
Chapter 5. The Builtin Classes

+n+ +-,length-+

Returns the receiving buffer with the characters of the target string beginning with character \( n \) for \( length \) characters converted to uppercase. If \( n \) is specified, it must be a positive whole number. If \( n \) is not specified, the case conversion will start with the first character. If \( length \) is specified, it must be a non-negative whole number. If \( length \) the default is to convert the remainder of the buffer.

5.4.14.34. verify

\[ \text{verify} \text{ } \text{reference} \rightarrow \text{start} \text{ } \text{length} \]

Returns a number that, by default, indicates whether the receiving buffer is composed only of characters from \( \text{reference} \). It returns 0 if all characters in the receiving buffer are in \( \text{reference} \) or returns the position of the first character in the receiving buffer not in \( \text{reference} \).

The \textit{option} can be either \texttt{Nomatch} (the default) or \texttt{Match}. (You need to specify only the first capitalized and highlighted letter; all characters following the first character are ignored, which can be in uppercase or lowercase.)

If you specify \texttt{Match}, the method returns the position of the first character in the receiving buffer that is in \( \text{reference} \), or returns 0 if none of the characters are found.

The default for \textit{start} is 1. Thus, the search starts at the first character of the receiving buffer. You can override this by specifying a different \textit{start} point, which must be a positive whole number.

The default for \textit{length} is the length of the buffer from \textit{start} to the end of the buffer. Thus, the search proceeds to the end of the receiving buffer. You can override this by specifying a different \textit{length}, which must be a non-negative whole number.

If the receiving string is null, the method returns 0, regardless of the value of the \textit{option}. Similarly, if \textit{start} is greater than \textit{receiving_buffer} length, the method returns 0. If \textit{reference} is null, the method returns 0 if you specify \texttt{Match}. Otherwise, the method returns the \textit{start} value.

Examples:

\[
\begin{align*}
\text{mutablebuffer} \text{ } \text{new}('123') \text{ } \text{verify}('1234567890') & \rightarrow 0 \\
\text{mutablebuffer} \text{ } \text{new}('123') \text{ } \text{verify}('1234567890') & \rightarrow 2 \\
\text{mutablebuffer} \text{ } \text{new}('AB4T') \text{ } \text{verify}('1234567890') & \rightarrow 1 \\
\text{mutablebuffer} \text{ } \text{new}('AB4T') \text{ } \text{verify}('1234567890','M') & \rightarrow 3 \\
\text{mutablebuffer} \text{ } \text{new}('AB4T') \text{ } \text{verify}('1234567890','N') & \rightarrow 1 \\
\text{mutablebuffer} \text{ } \text{new}('1P3Q4') \text{ } \text{verify}('1234567890', ,3) & \rightarrow 4 \\
\text{mutablebuffer} \text{ } \text{new}('123') \text{ } \text{verify}('',N,2) & \rightarrow 2 \\
\text{mutablebuffer} \text{ } \text{new}('ABCDE') \text{ } \text{verify}('', ,3) & \rightarrow 3 \\
\text{mutablebuffer} \text{ } \text{new}('AB3CDS') \text{ } \text{verify}('1234567890', ,4) & \rightarrow 6 \\
\text{mutablebuffer} \text{ } \text{new}('ABCD') \text{ } \text{verify}('ABC','N',2,3) & \rightarrow 4 \\
\text{mutablebuffer} \text{ } \text{new}('ABCD') \text{ } \text{verify}('ADEF','M',2,3) & \rightarrow 4
\end{align*}
\]
5.4.14.35. word

>>-word(n)-----------------------------------------------------><

Returns the \textit{n}th whitespace-delimited word in the receiving buffer or the null string if the receiving buffer has fewer than \textit{n} words. The \textit{n} must be a positive whole number. This method is exactly equivalent to \texttt{receiving\_buffer~subWord(n,1)}.

5.4.14.36. wordIndex

>>-wordIndex(n)------------------------------------------------><

Returns the position of the first character in the \textit{n}th whitespace-delimited word in the receiving buffer. It returns 0 if the receiving buffer has fewer than \textit{n} words. The \textit{n} must be a positive whole number.

5.4.14.37. wordLength

>>-wordLength(n)-----------------------------------------------><

Returns the length of the \textit{n}th whitespace-delimited word in the receiving buffer or 0 if the receiving buffer has fewer than \textit{n} words. The \textit{n} must be a positive whole number.

5.4.14.38. wordPos

>>-wordPos(phrase-+--------+-)---------------------------------><

Returns the word number of the first word of \textit{phrase} found in the receiving buffer, or 0 if \textit{phrase} contains no words or if \textit{phrase} is not found. Multiple whitespace characters between words in either \textit{phrase} or the receiving buffer are treated as a single blank for the comparison, but, otherwise, the words must match exactly.

By default the search starts at the first word in the receiving buffer. You can override this by specifying \texttt{start} (which must be positive), the word at which the search is to be started.

5.4.14.39. words

>>-words-------------------------------------------------------><

Returns the number of whitespace-delimited words in the receiving buffer.

5.4.15. The RegularExpression Class

This class provides support for regular expressions. A regular expression is a pattern you can use to match strings.
Chapter 5. The Builtin Classes

**Note:** The RegularExpression class is not a built-in class and is NOT preloaded. It is defined in the `rxregexp.cls` file. This means you must use a `::requires` statement to activate its functionality, as follows:

```
::requires "rxregexp.cls"
```

**Figure 5-42. The RegularExpression class and methods**

```
<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>RegularExpression</td>
</tr>
<tr>
<td>::requires rxregexp.cls</td>
</tr>
<tr>
<td>Init</td>
</tr>
<tr>
<td>match</td>
</tr>
<tr>
<td>parse</td>
</tr>
<tr>
<td>pos</td>
</tr>
<tr>
<td>position</td>
</tr>
</tbody>
</table>
```

**Note:** The RegularExpression class also has available class methods that its metaclass, the **Class class**, defines.

Here is a description of the syntax:

- `|` OR operator between the left and right expression
- `?` Matches any single character
- `*` Matches the previous expression zero or more times
- `+` Matches the previous expression one or more times
- `\` "Escape" symbol: use the next character literally
- `()` Expression in parenthesis (use where needed)
- `{n}` Matches previous expression n times (n>1)
Set definition: matches any single character out of the defined set. A `^` right after the opening bracket means that none of the following characters should be matched. A `-` (if not used with `\`) defines a range between the last specified character and the one following `-`. If it is the first character in the set definition, it is used literally.

The following symbolic names (they must start and end with `:`) can be used to abbreviate common sets:

- **:ALPHA:** Characters in the range A-Z and a-z
- **:LOWER:** Characters in the range a-z
- **:UPPER:** Characters in the range A-Z
- **:DIGIT:** Characters in the range 0-9
- **:ALNUM:** Characters in :DIGIT: and :ALPHA:
- **:XDIGIT:** Characters in :DIGIT:, A-F and a-f
- **:BLANK:** Space and tab characters
- **:SPACE:** Characters "09"x to "0D"x and space
- **:CNTRL:** Characters "00"x to "1F"x and "7F"x
- **:PRINT:** Characters in the range "20"x to "7E"x
- **:GRAPH:** Characters in :PRINT: without space
- **:PUNCT:** All :PRINT: characters without space and not in :ALNUM:

**Examples:**

::requires "rxregexp.cls"

"(Hi|Hello) World" Matches "Hi World" and "Hello World".

"file.??" Matches any file with three characters after ".".

"file.?{3}" Same as above.

"a *b" Matches all strings that begin with "a" and end with "b" and have an arbitrary number of spaces in between both.

"a +b" Same as above, but at least one space must be present.

"file.[bd]at" Matches "file.bat" and "file.dat".

"[A-Za-z]+" Matches any string containing only letters.

"[:ALPHA:]+" Same as above, using symbolic names.

"[^0-9]+" Matches any string containing no numbers, including the empty string.

"[:DIGIT::LOWER:]" A single character, either a digit or a lower case character.
Chapter 5. The BuiltinClasses

"This is (very )+nice." Matches all strings with one or more occurrences of "very " between "This is " and "nice.".

5.4.15.1. Inherited Methods

Methods inherited from the Object class.

new (class method)  instanceMethod  send
= \ === \== < > <
instanceMethods  sendWith
class  isA  setMethod
copy  isInstanceOf  start
defaultName  objectName  startWith
hasMethod  objectName=  string
identityHash  Request  unsetMethod
init  Run

5.4.15.2. init

+-,-"MAXIMAL"--+
>>-init(--+-+---------+-+--------------+-)--------------------><
+-Pattern+++-,-"MINIMAL"--+

Instantiates a RegularExpression object. Use the optional parameter Pattern to define a pattern that is used to match strings. See the introductory text below for a description of the syntax. If the strings match, you can decide whether you want to apply "greedy" matching (a maximum-length match) or "non-greedy" matching (a minimum-length match).

Examples:

myRE1 = .RegularExpression~new
myRE2 = .RegularExpression~new("Hello?*)

5.4.15.3. match

>>-match(-string-)-----------------------------------------><

This method tries to match string to the regular expression that was defined on the "new" invocation or on the "parse" invocation. It returns 0 on an unsuccessful match and 1 on a successful match. For an example see Parse.

5.4.15.4. parse

+-,-"CURRENT"--+
>>-parse(--+-+--------------+-)------------------------><
+-,-"MAXIMAL"--+
+-,-"MINIMAL"--+
This method creates the matcher used to match a string from the regular expression specified with `Pattern`. The `RegularExpression` object uses this regular expression until a new invocation of `Parse` takes place. The second (optional) parameter specifies whether to use minimal or maximal matching. The default is to use the current matching behavior.

**Return values:**

0

Regular expression was parsed successfully.

1

An unexpected symbol was met during parsing.

2

A missing ')' was found.

3

An illegal set was defined.

4

The regular expression ended unexpectedly.

5

An illegal number was specified.

**Example 1:**

```plaintext
a.0 = "does not match regular expression"
.a.1 = "matches regular expression"
b = .array~of("This is a nice flower.",
            "This is a yellow flower.", ,
            "This is a blue flower.",
            "Hi there!")

myRE = .RegularExpression~new
.e = myRE~parse("This is a ???? flower.")
if e == 0 then do
  do i over b
    j = myRE~match(i)
    say i~left(24) ">>" a.j
  end
end
else
  say "Error" e "occurred!"
exit

::requires "rxregexp.cls"

```
Output:
```

```
Chapter 5. The Builtin Classes

This is a nice flower.  >> Does match regular expression
This is a yellow flower.  >> Does not match regular expression
This is a blue flower.  >> Does match regular expression
Hi there!  >> Does not match regular expression

Example 2:

a.0 = "an invalid number!"
a.1 = "a valid number."
b = .array~of("1","42","0","5436412","1a","f43g")
myRE = .RegularExpression~new("[1-9][0-9]*")
do i over b
  j = myRE~match(i)
  say i "is" a.j
end
say

/* Now allow "hex" numbers and a single 0 */
if myRE~parse("0|([1-9a-f][0-9a-f]*)") == 0 then do
  do i over b
    j = myRE~match(i)
    say i "is" a.j
  end
  end
else
  say "invalid regular expression!"
end

::requires "rxregexp.cls"

Example 3:

str = "<p>Paragraph 1</p><p>Paragraph 2</p>"
myRE1 = .RegularExpression~new("<p>??</p>","MINIMAL")
myRE1~match(str)
myRE2 = .RegularExpression~new("<p>??</p>","MAXIMAL")
myRE2~match(str)
say "myRE1 (minimal) matched" str~substr(1,myRE1~position)
say "myRE2 (maximal) matched" str~substr(1,myRE2~position)

::requires "rxregexp.cls"

Output:

myRE1 (minimal) matched <p>Paragraph 1</p>
myRE2 (maximal) matched <p>Paragraph 1</p><p>Paragraph 2</p>
5.4.15.5. pos

This method tries to locate a string defined by the regular expression on the "new" invocation or on the "parse" invocation in the given haystack string. It returns 0 on an unsuccessful match or the starting position on a successful match. The end position of the match can be retrieved with the position method.

Example:

```ruby
str = "It is the year 2002!"
myRE = .RegularExpression~new("[1-9][0-9]*")
begin = myRE~pos(str)
if begin > 0 then do
  year = str~substr(begin, myRE~position - begin + 1)
  say "Found the number" year "in this sentence."
end
::requires "rxregexp.cls"
```

Output:

Found the number 2002 in this sentence.

5.4.15.6. position

Returns the character position at which the last parse(), pos(), or match() method ended.

Example:

```ruby
myRE = .RegularExpression~new
myRE~parse("[abc"]") -- illegal set definition
say myRE~position -- will be 4

myRE = .RegularExpression~new("[abc]12")
myRE~match("c12")
say myRE~position -- will be 3

myRE~match("a13")
say myRE~position -- will be 2 (failure to match)
::requires "rxregexp.cls"
```

5.4.16. The RexxQueue Class

The RexxQueue class provides object-style access to Rexx external data queues.
Figure 5-43. The RexxQueue class and methods

Note: The RexxQueue class also has available class methods that its metaclass, the Class class, defines.

5.4.16.1. Inherited Methods

Methods inherited from the Object class.

<table>

</tr>
<tr>
<td>unsetMethod</td>
<td></td>
</tr>
</tbody>
</table>
5.4.16.2. create (Class Method)

```bash
>>-create(name)--------------------------------------------><
```
Attempts to create an external Rexx named queue using `name`. If a `name` queue already exists, a new queue with a Rexx-generated name will be created. This method returns the name of the created queue, which will be either `name`, or a generated name if there is a conflict.

5.4.16.3. delete (Class Method)

```bash
>>-delete(name)--------------------------------------------><
```
Attempts to delete an external Rexx named queue named `name`. This method returns "0" if the queue was successfully deleted. Non-zero results are the error codes from the RexxDeleteQueue() programming interface.

5.4.16.4. exists (Class Method)

```bash
>>-exists(name)--------------------------------------------><
```
Tests if an external Rexx queue `name` currently exists, returning 1 (true) if it does and 0 (false) otherwise.

5.4.16.5. open (Class Method)

```bash
>>-open(name)--------------------------------------------><
```
Tests if the external Rexx named queue `name` exists and creates the queue if it does not.

5.4.16.6. delete

```bash
>>-delete--------------------------------------------><
```
Deletes the Rexx external queue associated with this RexxQueue instance.

5.4.16.7. empty

```bash
>>-empty--------------------------------------------><
```
Removes all items from the Rexx external queue associated with this RexxQueue instance.

5.4.16.8. get

```bash
>>-get--------------------------------------------><
```
Returns the name of the Rexx external queue associated with this instance.
Chapter 5. The Builtin Classes

5.4.16.9. init

```
>>-init(-+------+-)----------------------------------><
  +-name+-
```

Initializes a new RexxQueue instance associated with the named Rexx external queue. If `name` is not specified, the SESSION queue is used. If the named queue does not exist, one will be created.

5.4.16.10. lineIn

```
>>-lineIn--------------------------------------------------><
```

Reads a single line from the Rexx external queue. If the queue is empty, `lineIn` will wait until a line is added to the queue.

5.4.16.11. lineOut

```
>>-lineOut(-+------+-)----------------------------------><
  +-line+-
```

Adds a line to the Rexx external queue in first-in-first-out (FIFO) order. If `line` is not specified, a null string (""") is added.

5.4.16.12. makeArray

```
>>-makeArray---------------------------------------------><
```

Returns a single-index array with the same number of items as the receiver object. Items in the new array will have the same order as the items in the external queue. The external queue is emptied.

5.4.16.13. pull

```
>>-pull--------------------------------------------------><
```

Reads a line from the Rexx external queue. If the queue is currently empty, this method will immediately return the Nil Object without waiting for lines to be added to the queue.

5.4.16.14. push

```
>>-push(-+------+-)----------------------------------><
  +-line+-
```

Adds a line to the Rexx external queue in last-in-last-out (LIFO) order. If `line` is not specified, a null string (""") is added.
5.4.16.15. queue

```
>>-queue(-+------+-)----------------------------------><
   +-line+-
```

Adds a line to the Rexx external queue in first-in-first-out (FIFO) order. If `line` is not specified, a null string (""") is added.

5.4.16.16. queued

```
>>-queued---------------------------------------------><
```

Returns the count of lines currently in the Rexx external queue.

5.4.16.17. say

```
>>-say(-+------+-)----------------------------------><
   +-line+-
```

Adds a line to the Rexx external queue in first-in-first-out (FIFO) order. If `line` is not specified, a null string (""") is added.

5.4.16.18. set

```
>>-set(name)----------------------------------><
```

Switches the Rexx external queue associated with the RexxQueue instance. The new queue must have been previously created. The method return value is the name of current queue being used by the instance.

5.4.17. The Supplier Class

You can use a supplier object to iterate over items of a collection. Supplier objects are created from a snapshot of a collection. The iteration results are not affected by later changes to the source collection object.
Figure 5-44. The Supplier class and methods

```
+-------------------+-----------------
| Object            | Supplier        |
|                   | new             |
| allIndexes        | allItems        |
| available         | getArrays       |
| index             | init            |
| items             | next            |
| supplier          |                 |
```

**Note:** The Supplier class also has available class methods that its metaclass, the Class class, defines.

### 5.4.17.1. Inherited Methods

Methods inherited from the Object class.

- new (class method)
- = <= => <= <> ><
- class
- copy
- defaultName
- hasMethod
- identityHash
- init
- instanceMethod
- instanceMethods
- isA
- isInstanceOf
- methodName
- objectName
- Request
- Run

### 5.4.17.2. new (Class Method)

```
>>new(items,indexes)-----------------------------------------><
```

Returns a new supplier object. The items argument must be an array of objects over which the supplier iterates. The indexes argument is an array of index values with a one-to-one correspondence to the objects contained in the items array. The created supplier iterates over the arrays, returning elements of

350 ooRexx Reference Version 4.0.0
the values array in response to **items** messages, and elements of the indexes array in response to **index** messages. The supplier iterates for the number of items contained in the values array, returning the Nil object for any nonexistent items in either array.

### 5.4.17.3. allIndexes

>>-allIndexes--------------------------------------------------------<

Returns an array of all index values from the current supplier position to the end of the supplier. Once **allIndexes** is called, no additional items can be retrieved from the supplier. Calls to **available** will return "0" (false).

### 5.4.17.4. allItems

>>-allItems--------------------------------------------------------<

Returns an array of all items from the current supplier position to the end of the supplier. Once **allItems** is called, no additional items can be retrieved from the supplier. Calls to **available** will return "0" (false).

### 5.4.17.5. available

>>-available---------------------------------------------------><

Returns 1 (true) if an item is available from the supplier (that is, if the **item** method would return a value). It returns 0 (false) if the collection is empty or the supplier has already enumerated the entire collection.

### 5.4.17.6. index

>>-index-------------------------------------------------------><

Returns the index of the current item in the collection. If no item is available, that is, if **available** would return false, the supplier raises an error.

### 5.4.17.7. init

>>-init--------------------------------------------------------><

Initializes the object instance.

### 5.4.17.8. item

>>-item--------------------------------------------------------><
Chapter 5. The Builtin Classes

Returns the current item in the collection. If no item is available, that is, if `available` would return false, the supplier raises an error.

5.4.17.9. next

```
next
```

Moves to the next item in the collection. By repeatedly sending `next` to the supplier (as long as `available` returns true), you can enumerate all items in the collection. If no item is available, that is, if `available` would return false, the supplier raises an error.

5.4.17.10. Examples

desserts=.array~of(apples, peaches, pumpkins, 3.14159) /* Creates array */
say "The desserts we have are:"
baker=desserts~supplier /* Creates supplier object named BAKER */
do while baker~available /* Array suppliers are sequenced */
  if baker~index=4
    then say baker~item "is pi, not pie!!!"
  else say baker~item
  baker~next
end

/* Produces: */
/* The desserts we have are: */
/* APPLES */
/* PEACHES */
/* PUMPKINS */
/* 3.14159 is pi, not pie!!! */

5.4.17.11. supplier

```
supplier
```

Returns the target supplier as a result. This method allows an existing supplier to be passed to methods that expect an object that implements a `supplier` method as an argument.

5.4.18. The StreamSupplier Class

A subclass of the `Supplier` class that will provided stream lines using supplier semantics. This allows the programmer to iterate over the remaining lines in a stream. A `StreamSupplier` object provides a snapshot of the stream at the point in time it is created, including the current line read position. In general, the iteration is not effected by later changes to the read and write positioning of the stream. However, forces external to the iteration may change the content of the remaining lines as the iteration progresses.
Figure 5-45. The StreamSupplier class and methods

<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supplier</td>
</tr>
<tr>
<td>StreamSupplier</td>
</tr>
</tbody>
</table>

- available
- index
- init
- item
- next

**Note:** The StreamSupplier class also has available class methods that its metaclass, the Class class, defines.

### 5.4.18.1. Inherited Methods

Methods inherited from the Object class.

- new (class method)
- \=` \== \\= \== <\> >><
- class
- copy
- defaultName
- hasMethod
- identityHash
- init
- instanceMethod
- instanceMethods
- isA
- isInstanceOf
- objectName
- objectName=
- Request
- Run
- send
- sendWith
- setMethod
- start
- startWith
- string
- unsetMethod

Methods inherited from the Supplier class.

- new (class method)
- available
- item
- allIndexes
- index
- next
- allItems
- init
- supplier

### 5.4.18.2. available

```plaintext
>>-available-----------------------------------------------><
```

Returns 1 (true) if an item is available from the supplier (that is, if the item method would return a value). It returns 0 (false) if the collection is empty or the supplier has already enumerated the entire collection.
Chapter 5. The Built-in Classes

5.4.18.3. index

>>-index-------------------------------------------------------><

Returns the index of the current item in the collection. If no item is available, that is, if available would return false, the supplier raises an error.

5.4.18.4. init

>>-init--------------------------------------------------------><

Initializes the object instance.

5.4.18.5. item

>>-item--------------------------------------------------------><

Returns the current item in the collection. If no item is available, that is, if available would return false, the supplier raises an error.

5.4.18.6. next

>>-next--------------------------------------------------------><

Moves to the next item in the collection. By repeatedly sending next to the supplier (as long as available returns true), you can enumerate all items in the collection. If no item is available, that is, if available would return false, the supplier raises an error.

5.4.19. The RexxContext Class

The RexxContext class gives access to context information about the currently executing Rexx code. Instances of the RexxContext class can only be obtained via the .CONTEXT environment symbol. They cannot be directly created by the user. It is a subclass of the Object class.
5.4.19.1. Inherited Methods

Methods inherited from the Object class.

- new (class method)
- = != \= \== < <= > >=
- class
- copy
- defaultName
- hasMethod
- identityHash
- init
- instanceMethod
- instanceMethods
- isA
- isInstanceOf
- objectName
- objectName=
- Request
- Run
- send
- sendWith
- setMethod
- start
- startWith
- string
- unsetMethod

5.4.19.2. args

>>>args----------------------------------------------------------<<<

Returns the arguments used to invoke the current context as an array. This is equivalent to using the Arg(1, 'A') built-in function.

5.4.19.3. condition

>>>condition------------------------------------------------------<<<
Chapter 5. The Built-in Classes

Returns the current context condition object, or the Nil object if the context does not currently have a trapped condition. This is equivalent to using the Condition('O') built-in function.

5.4.19.4. digits

>>-digits------------------------------------------------------<

Returns the current context digits setting. This is equivalent to using the digits() built-in function.

5.4.19.5. executable

>>-executable--------------------------------------------------<

Returns the current executable object for the current context. The executable will be either a Routine or Method object, depending on the type of the active context.

5.4.19.6. form

>>-form-------------------------------------------------------<

Returns the current context form setting. This is equivalent to using the form() built-in function.

5.4.19.7. fuzz

>>-fuzz------------------------------------------------------<

Returns the current context fuzz setting. This is equivalent to using the fuzz() built-in function.

5.4.19.8. line

>>-line------------------------------------------------------<

Returns the context current execution line. This is equivalent to using the .LINE environment symbol.

5.4.19.9. package

>>-package-----------------------------------------------------<

Returns the Package object associated with the current executable object.

5.4.19.10. rs

>>-rs---------------------------------------------------------<
Returns the context current return status value. If no host commands have been issued in the current context, the Nil object is returned. This is equivalent to using the .RS environment symbol.

### 5.4.19.11. variables

```>>-variables----------------------------------------------<<
```

Returns a directory object containing all of the variables in the current execution context. The directory keys will be the variable names and the mapped values are the values of the variables. The directory will only contain simple variables and stem variables. Compound variable values may be accessed by using the stem objects that are returned for the stem variable names.

### 5.4.20. The WeakReference Class

A WeakReference instance maintains a non-pinning reference to another object. A non-pinning reference does not prevent an object from getting garbage collected or having its uninit method run when there are no longer normal references maintained to the object. Once the referenced object is eligible for garbage collection, the reference inside the WeakReference instance will be cleared and the VALUE method will return .nil on all subsequent calls. WeakReferences are useful for maintaining caches of objects without preventing the objects from being reclaimed by the garbage collector when needed.

Figure 5-47. The WeakReference class and methods

```
<table>
<thead>
<tr>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>WeakReference</td>
</tr>
<tr>
<td>new</td>
</tr>
<tr>
<td>value</td>
</tr>
</tbody>
</table>
```

**Note:** The WeakReference class also has available class methods that its metaclass, the Class class, defines.
5.4.20.1. Inherited Methods

Methods inherited from the Object class.

new (class method) instanceMethod send
= \== \== \<< \>>
class isa instanceof setMethod
copy isInstanceOf start
defaultName objectName startWith
hasMethod objectName= string
identityHash Request unsetMethod
init Run

5.4.20.2. new (Class Method)

>>-new-(object)------------------------------------------------><

Returns a new WeakReference instance containing a reference to object.

5.4.20.3. value

>>-value------------------------------------------------><

This method returns the referenced object. If the object has been garbage collected, then the Nil object is returned.

5.4.21. The Pointer Class

Figure 5-48. The Pointer class and methods

```
  Object
  |
  WeakReference
  |
  new
  |
  value
```
A Pointer instance is a wrapper around a native pointer value. This class is designed primarily for writing methods and functions in native code and can only be created using the native code application programming interfaces. The Pointer class new method will raise an error if invoked.

**Note:** The Pointer class also has available class methods that its metaclass, the Class class, defines.

### 5.4.21.1. Inherited Methods

Methods inherited from the Object class.

<table>
<thead>
<tr>
<th>new (class method)</th>
<th>instanceMethod</th>
<th>send</th>
</tr>
</thead>
<tbody>
<tr>
<td>=, &lt;=, ==, =&gt;, &lt;=</td>
<td>instanceMethods</td>
<td>sendWith</td>
</tr>
<tr>
<td>class</td>
<td>isA</td>
<td>setMethod</td>
</tr>
<tr>
<td>copy</td>
<td>isInstanceOf</td>
<td>start</td>
</tr>
<tr>
<td>defaultName</td>
<td>objectName</td>
<td>startWith</td>
</tr>
<tr>
<td>hasMethod</td>
<td>objectName=</td>
<td>string</td>
</tr>
<tr>
<td>identityHash</td>
<td>Request</td>
<td>unsetMethod</td>
</tr>
<tr>
<td>init</td>
<td>Run</td>
<td></td>
</tr>
</tbody>
</table>

### 5.4.21.2. new (Class Method)

> new--------------------------------------------------------><

Creating Pointer object instances directly from Rexx code is not supported. The Pointer class new method will raise an error if invoked.

### 5.4.21.3. Operator Methods

> comparison_operator(argument)-----------------------------><

Returns 1 (true) or 0 (false), the result of performing a specified comparison operation.

For the Pointer class, the argument object must be a pointer object instance and the wrappered pointer value must be the same.

The comparison operators you can use in a message are:

- `=, ==` True if the wrappered pointer values are the same.
- `\=, <, <=, \=, <=` True if the wrappered pointer values are not the same.

### 5.4.21.4. isNull

> isNull-----------------------------------------------------><

Returns 1 (true) if the wrappered pointer value is a NULL pointer (0) value. Returns 0 (false) if the
5.4.22. The Buffer Class

A Buffer instance is a Rexx interpreter managed block of storage. This class is designed primarily for writing methods and functions in native code and can only be created using the native code application programming interfaces. The Buffer class new method will raise an error if invoked.

**Note:** The Buffer also has available class methods that its metaclass, the Class class, defines.

5.4.22.1. Inherited Methods

Methods inherited from the Object class.

- new (class method)
- = <= \= \<= <> >> <<
- class
- copy
- defaultName
- hasMethod
- identityHash
- init
- instanceMethod
- instanceMethods
- isA
- isInstanceOf
- objectName
- objectName=
- Request
- Run
- send
- sendWith
- setMethod
- start
- startWith
- string
- unsetMethod

5.4.22.2. new (Class Method)

```bash
>>>new-->--------------------------------------------->
```
Creating Buffer object instances directly from Rexx code is not supported. The Buffer class new method will raise an error if invoked.
Chapter 5. The Builtin Classes
Chapter 6. Rexx Runtime Objects

In addition to the class objects described in the previous chapter, the Rexx runtime environment also provides objects that are accessible via environment symbols (see Environment Symbols).

6.1. The Environment Directory (.ENVIRONMENT)

The Environment object is a directory of public objects that are always accessible. The Environment object is automatically searched when environment symbols are used, or the Environment object may be directly accessed using the .ENVIRONMENT symbol. Entries stored in the Environment use the same name as the corresponding environment symbol, but without a leading period. For example:

```plaintext
say .true -- Displays "1"
say .environment~true -- Also displays "1"
```

The Environment object directory contains all of the Rexx built-in classes (Array, etc.), plus special Rexx constants such as .NIL, .TRUE, and .FALSE.

6.1.1. The ENDOFLINE Constant (.ENDOFLINE)

The ENDOFLINE object is a string constant representing the line terminator used for file line end markers for a given system. This constant is "0d0a"x on Windows (carriage return/linefeed) and "0a"x (linefeed) on Unix platforms.

6.1.2. The FALSE Constant (.FALSE)

The FALSE object is the constant "0" representing a FALSE result for logical and comparison operations.

6.1.3. The NIL Object (.NIL)

The Nil object is a special object that does not contain data. It usually represents the absence of an object, as a null string represents a string with no characters. It has only the methods of the Object class. Note that you use the Nil object (rather than the null string ("")) to test for the absence of data in an array or other Collection class entry:

```plaintext
if .nil = board[row,col] /* .NIL rather than "" */
then ...
```

6.1.4. The TRUE Constant (.TRUE)

The TRUE object is the constant "1", representing a true result for logical and comparison operations.
6.2. The Local Directory (.LOCAL)

The Local environment object is a directory of interpreter instance objects that are always accessible. You can access objects in the Local environment object in the same way as objects in the Environment object. The Local object contains the .INPUT, .OUTPUT, and .ERROR Monitor objects used for Rexx console I/O, the .STDIN, .STDOUT, and .STDERR output streams that are the default I/O targets, and the .STDQUE RexxQueue instance used for Rexx external queue operations.

Because both .ENVIRONMENT and .LOCAL are directory objects, you can place objects into, or retrieve objects from, these environments by using any of the directory methods ([],[]=, PUT, AT, SETENTRY, ENTRY, or SETMETHOD). To avoid potential name clashes with built-in objects and public objects that Rexx provides, each object that your programs add to these environments should have a period in its index.

Examples:

```rex
/* .LOCAL example--places something in the Local environment directory */
.local~my.alarm = theAlarm
/* To retrieve it */
say .local~my.alarm

/* Another .LOCAL example (Windows) */
.environment["MYAPP.PASSWORD"] = "topsecret"
.environment["MYAPP.UID"] = 200

/* Create a local directory for my stuff */
.MYAPP.LOCAL] = .directory~new

/* Add log file for my local directory */
.myapp.local["LOG"] = .stream~new("myapp.log")
say .myapp.password /* Displays "topsecret" */
say .myapp.uid /* Displays "200" */

/* Write a line to the log file */
.myapp.local["LOG"]~lineout("Logon at ",time()," on ",date())

/* Redirect SAY lines into a file: */
.output~destination(.stream~new("SAY_REDIRECT.TXT"))
say "This goes into a file, and not onto the screen!"
```

6.3. The Error Monitor (.ERROR)

This monitor object (see The Monitor Class) holds the trace stream object. You can redirect the trace output in the same way as with the output object in the Monitor class example.

The default for this object’s initial destination is the .STDERR stream.
6.4. The Input Monitor (.INPUT)

This monitor object (see The Monitor Class) holds the default input stream object (see Input and Output Streams). This input stream is the source for the PARSE LINEIN instruction, the LINEIN method of the Stream class, and, if you specify no stream name, the LINEIN built-in function. It is also the source for the PULL and PARSE PULL instructions if the external data queue is empty.

The default for this object’s initial source is the .STDIN stream.

6.5. The Output Monitor (.OUTPUT)

This monitor object (see The Monitor Class) holds the default output stream object (see Input and Output Streams). This is the destination for output from the SAY instruction, the LINEOUT method (.OUTPUT~LINEOUT), and, if you specify no stream name, the LINEOUT built-in function. You can replace this object in the environment to direct such output elsewhere (for example, to a transcript window).

The default for this object’s initial destination is the .STDOUT stream.

6.6. The STDERR Stream (.STDERR)

This stream object (see The Stream Class) is the default stream used for trace and error message output.

6.7. The STDIN Stream (.STDIN)

This is the stream object (see The Stream Class) representing the standard input file of a process. It is the startup default stream for the .INPUT object.

6.8. The STDOUT Stream (.STDOUT)

This is the stream object (see The Stream Class) representing the standard output file of a process. It is the startup default stream for the .OUTPUT object.

6.9. The STDQUE Queue (.STDQUE)

This RexxQueue object (see The RexxQueue Class) is the destination for the PUSH and QUEUE instruction, and the source for queue lines for the PULL and PARSE PULL instructions.
6.10. The Rexx Context (.CONTEXT)

The .CONTEXT environment symbol accesses a RexxContext instance for the currently active Rexx execution environment. See The RexxContext Class for details on the RexxContext object. The returned context object is only active until the current method call, routine call, or program terminates. Once the context object is deactivated, an error will be raised if any of the RexxContext methods are called.

6.11. The Line Number (.LINE)

.LINE is set to the line number of the instruction currently being executed. If the current instruction is defined within an INTERPRET instruction, the line number of INTERPRET instruction is returned.

6.12. The METHODS Directory (.METHODS)

The .METHODS environment symbol identifies a directory (see The Directory Class) of methods that ::METHOD directives in the currently running program define. The directory indexes are the method names. The directory values are the method objects. See The Method Class.

Only methods and/or attributes that are not preceded by a ::CLASS directive are in the .METHODS directory. These are known as floating methods. If there are no such methods, the .METHODS symbol has the default value of .METHODS.

Example:

```rexx
/* .methods contains one entry with the index (method name) "TALK" */
o=.object~enhanced(.methods) /* create object, enhance it with methods */
o~talk("echo this text") /* test "TALK" method */
::method talk /* floating method by the name of "TALK" */
  use arg text /* retrieve the argument */
  say text /* display received argument */
```

6.13. The Return Status (.RS)

.RS is set to the return status from any executed command (including those submitted with the ADDRESS instruction). The .RS environment symbol has a value of -1 when a command returns a FAILURE condition, a value of 1 when a command returns an ERROR condition, and a value of 0 when a command indicates successful completion. The value of .RS is also available after trapping the ERROR or FAILURE condition.

Note: Commands executed manually during interactive tracing do not change the value of .RS. The initial value of .RS is .RS.
Chapter 7. Functions

A function is an internal, built-in, or external routine that returns a single result object. (A subroutine is a function that is an internal, built-in, or external routine that might return a result and is called with the CALL instruction.)

7.1. Syntax

A function call is a term in an expression calling a routine that carries out some procedures and returns an object. This object replaces the function call in the continuing evaluation of the expression. You can include function calls to internal and external routines in an expression anywhere that a data term (such as a string) would be valid, using the following notation:

```
+-,------------------+
|                     |
>>-function_name(----+------------+-+--)-----------------------><
 +expression+-
```

The `function_name` is a literal string or a single symbol, which is taken to be a constant.

There can be any number of expressions, separated by commas, between the parentheses. These expressions are called the arguments to the function. Each argument expression can include further function calls.

Note that the left parenthesis must be adjacent to the name of the function, with no whitespace characters between. (A blank operator would be assumed at this point instead.) Only a comment can appear between the name and the left parenthesis.

The arguments are evaluated in turn from left to right and the resulting objects are then all passed to the function. This function then runs some operation (usually dependent on the argument objects passed, though arguments are not mandatory) and eventually returns a single object. This object is then included in the original expression as though the entire function reference had been replaced by the name of a variable whose value is the returned object.

For example, the function `SUBSTR` is built into the language processor and could be used as:

```
N1="abcdefghijk"
Z1="Part of N1 is: "substr(N1,2,7)
/* Sets Z1 to "Part of N1 is: bcdefgh" */
```

A function can have a variable number of arguments. You need to specify only those required. For example, `SUBSTR("ABCDEF",4)` would return `DEF`.

7.2. Functions and Subroutines

Functions and subroutines are called in the same way. The only difference between functions and subroutines is that functions must return data, whereas subroutines need not.

The following types of routines can be called as functions:
Chapter 7. Functions

Internal

If the routine name exists as a label in the program, the current processing status is saved for a later return to the point of invocation to resume execution. Control is then passed to the first label in the program that matches the name. As with a routine called by the CALL instruction, status information, such as TRACE and NUMERIC settings, is saved too. See the CALL instruction (CALL) for details.

If you call an internal routine as a function, you must specify an expression in any RETURN instruction so that the routine can return. This is not necessary if it is called as a subroutine.

Example:

/* Recursive internal function execution... */
arg x
say x"! =" factorial(x)
exit

factorial: procedure /* Calculate factorial by */
  arg n /* recursive invocation. */
  if n=0 then return 1
  return factorial(n-1) * n

FACTORIAL is unusual in that it calls itself (this is recursive invocation). The PROCEDURE instruction ensures that a new variable n is created for each invocation.

Built-in

These functions are always available and are defined in Built-in Functions.

External

You can write or use functions that are external to your program and to the language processor. An external routine can be written in any language, including Rexx, that supports the system-dependent interfaces the language processor uses to call it. You can call a Rexx program as a function and, in this case, pass more than one argument string. The ARG, PARSE ARG, or USE ARG instruction or the ARG built-in function can retrieve these argument strings. When called as a function, a program must return data to the caller.

Notes:

1. Calling an external Rexx program as a function is similar to calling an internal routine. For an external routine, however, the caller’s variables are hidden. To leave the called Rexx program, you can use either EXIT or RETURN. In either case, you must specify an expression.

2. You can use the INTERPRET instruction to process a function with a variable function name. However, avoid this if possible because it reduces the clarity of the program.

7.2.1. Search Order

Functions are searched in the following sequence: internal routines, built-in functions, external functions. Function calls or subroutines may use a name that is specified as a symbol or a literal string. For example, these calls are equivalent:
Chapter 7. Functions

Note that the name value when specified as a symbol is the symbol name translated to upper case. Both of the calls above will search for a routine named "MYPROCEDURE". When the name is specified as a literal string, then the literal string value is used as-is. Thus the following two calls are not equivalent:

```plaintext
call MyProcedure -- calls "MYPROCEDURE"
call 'MyProcedure' -- calls "MyProcedure"
```

Some steps of the function and subroutine search order are case sensitive, so some care may need to be exercised that the correct name form is used:

- **Internal routines.** Normally, labels are specified as a symbol followed by a ":". These labels have a name value that’s all uppercase. Since unquoted (symbol) names also have uppercase values, these will match easily. It is also possible to use literal strings for label names. If these labels contain lowercase characters, they will not be located using normal call mechanisms.

- **Built-in functions.** The built-in function names are all uppercase, so using a mixed-case literal string built-in function name will fail to locate the function.

```plaintext
x = wordPos(needle, haystack) -- calls "WORDPOS", which works
x = "wordPos"(needle, haystack) -- calls "wordPos", which will fail
```

- **External routines.** Some steps of the external function search order may be case sensitive, depending on the system. This may occasionally require a function or subroutine name to be specified as a mixed case literal string to be located.

If the call or function invocation uses a literal string, then the search for internal label is bypassed. This bypass mechanism allows you to extend the capabilities of an existing internal function, for example, and call it as a built-in function or external routine under the same name as the existing internal function. To call the target built-in or external routine from inside your internal routine, you must use a literal string for the function name.

**Example:**

```plaintext
/* This internal DATE function modifies the default for the DATE function to standard date. */
date: procedure
arg in
if in="" then in="Standard"
-- This calls the DATE built-in function rather than recursively
-- calling the DATE: internal routine. Note that the name needs to
-- be all uppercase because built-in functions have uppercase names.
return "DATE"(in)
```

Since built-in functions have uppercase names the literal string must also be in uppercase for the search to succeed.

External functions and subroutines have a system-defined search order.

The search order for external functions is as follows:

1. Functions defined on ::ROUTINE directives within the program.
2. Public functions defined on :ROUTINE directives of programs referenced with :REQUIRES.

3. Functions that have been loaded into the macrospace for preorder execution. (See the Open Object Rexx: Programming Guide for details.)

4. Functions that are part of a function package or library package. (See the Open Object Rexx: Programming Guide for details.)

5. Rexx functions located in an external file. See below for how these external files are located.

6. Functions that have been loaded into the macrospace for postorder execution.

7.2.1.1. Locating External Rexx Files

Rexx uses an extensive search procedure for locating program files. The first element of the search procedure is the locations that will be checked for files. The locations, in order of checking, are:

1. The same directory the program invoking the external routine is located. If this is an initial program execution or the calling program was loaded from the macrospace, this location is skipped. Checking in this directory allows related program files to be called without requiring the directory be added to the search path.

2. The current filesystem directory.

3. The current filesystem directory.

4. Some applications using Rexx as a scripting language may define an extension path used to locate called programs. If the Rexx program was invoked directly from the system command line, the no extension path is defined.

5. Any directories specified via the REXX_PATH environment variable.

6. Any directories specified via the PATH environment variable.

The second element of the search process is the file extension. If the routine name contains a period, then this routine is extension qualified. The search locations above will be checked for the target file unchanged, and no additional steps will be taken. If the routine name is not extension qualified, then additional searches will be performed by adding file extensions to the name. The following extensions may be used:

1. If the calling program has a file extension, then the interpreter will attempt to locate a file using the same extension as the caller. All directory locations will be checked for a given extension before moving to the next potential extension.

2. Some applications Rexx as a scripting language may define extensions that should be added to the search order. For example, an editor might define a preferred extension that should be used for editor macros. This extension would be searched next.

3. The default system extensions (.REX).

4. If the target file has not been located using any of the above extensions, the file name is tried without an added extension.

There are some system file system considerations involved when search for files. The Windows file system is case insensitive, so files can be located regardless of how the call is specified. Unix-based systems have a case sensitive file system, so files much be exact case matches in order to be located. For
these systems, each time a file name probe is attempted, the name will be tried in the case specified and also as a lower case name.
Chapter 7. Functions

Figure 7-1. Function and Routine Resolution and Execution

Start

Located on search path with original routine name?

yes

Proceed to next search step

yes

Execute
7.2.2. Errors during Execution

If an external or built-in function detects an error, the language processor is informed, and a syntax error results. Syntax errors can be trapped in the caller using SIGNAL ON SYNTAX and recovery might be possible. If the error is not trapped, the program is ended.

7.3. Return Values

A function usually returns a value that is substituted for the function call when the expression is evaluated.

How the value returned by a function (or any Rexx routine) is handled depends on whether it is called by a function call or as a subroutine with the CALL instruction.

- A routine called as a subroutine: If the routine returns a value, that value is stored in the special variable named RESULT. Otherwise, the RESULT variable is dropped, and its value is the string RESULT.
- A routine called as a function: If the function returns a value, that value is substituted in the expression at the position where the function was called. Otherwise, the language processor stops with an error message.

Here are some examples of how to call a Rexx procedure:

call Beep 500, 100 /* Example 1: a subroutine call */

The built-in function BEEP is called as a Rexx subroutine. The return value from BEEP is placed in the Rexx special variable RESULT.

bc = Beep(500, 100) /* Example 2: a function call */

BEEP is called as a Rexx function. The return value from the function is substituted for the function call. The clause itself is an assignment instruction; the return value from the BEEP function is placed in the variable bc.

Beep(500, 100) /* Example 3: result passed as */
/* a command */

The BEEP function is processed and its return value is substituted in the expression for the function call, like in the preceding example. In this case, however, the clause as a whole evaluates to a single expression. Therefore, the evaluated expression is passed to the current default environment as a command.

Note: Many other languages, such as C, throw away the return value of a function if it is not assigned to a variable. In Rexx, however, a value returned like in the third example is passed on to the current environment or subcommand handler. If that environment is the default, the operating system performs a disk search for what seems to be a command.
7.4. Built-in Functions

Rexx provides a set of built-in functions, including character manipulation, conversion, and information functions. The following are general notes on the built-in functions:

- The parentheses in a function are always needed, even if no arguments are required. The first parenthesis must follow the name of the function with no whitespace in between.
- The built-in functions internally work with NUMERIC DIGITS 9 for 32-bit systems or NUMERIC DIGITS 18 for 64-bit systems, and NUMERIC FUZZ 0 and are unaffected by changes to the NUMERIC settings, except where stated. Any argument named as a number is rounded, if necessary, according to the current setting of NUMERIC DIGITS (as though the number had been added to 0) and checked for validity before use. This occurs in the following functions: ABS, FORMAT, MAX, MIN, SIGN, and TRUNC, and for certain options of DATATYPE.
- Any argument named as a string can be a null string.
- If an argument specifies a length, it must be a positive whole number or zero. If it specifies a start character or word in a string, it must be a positive whole number, unless otherwise stated.
- If the last argument is optional, you can always include a comma to indicate that you have omitted it. For example, DATATYPE(1,), like DATATYPE(1), would return NUM. You can include any number of trailing commas; they are ignored. If there are actual parameters, the default values apply.
- If you specify a pad character, it must be exactly one character long. A pad character extends a string, usually on the right. For an example, see the LEFT built-in function LEFT.
- If a function has an option that you can select by specifying the first character of a string, that character can be in uppercase or lowercase.
- Many of the built-in functions invoked methods of the String class. For the functions ABBREV, ABS, BITAND, BITOR, BITXOR, B2X, CENTER, CENTRE, CHANGESTR, COMPARE, COPIES, COUNTSTR, C2D, C2X, DATATYPE, DELSTR, DELWORD, D2C, D2X, FORMAT, LEFT, LENGTH, LOWER, MAX, MIN, REVERSE, RIGHT, SIGN, SPACE, STRIP, SUBSTR, SUBWORD, TRANSLATE, TRUNC, UPPER, VERIFY, WORD, WORDINDEX, WORDLENGTH, WORDS, X2B, X2C, and X2D, the first argument to the built-in function is used as the receiver object for the message sent, and the remaining arguments are used in the same order as the message arguments. For example, SUBSTR("abcde",3,2) is equivalent to "abcde"~SUBSTR(3,2).
- The language processor evaluates all built-in function arguments to produce character strings.

7.4.1. ABBREV (Abbreviation)

```
>>>ABBREV(information,info+-+--------+-)---------------------------<
  +-,.length+-
```

Returns 1 if info is equal to the leading characters of information and the length of info is not less than length. It returns 0 if either of these conditions is not met.
Chapter 7. Functions

If you specify length, it must be a positive whole number or zero. The default for length is the number of characters in info.

Here are some examples:

ABBREV("Print","Pri") -> 1
ABBREV("PRINT","Pri") -> 0
ABBREV("PRINT","PRI",4) -> 0
ABBREV("PRINT","PRY") -> 0
ABBREV("PRINT",""") -> 1
ABBREV("PRINT","",1) -> 0

Note: A null string always matches if a length of 0, or the default, is used. This allows a default keyword to be selected automatically if desired; for example:

    say "Enter option:"; pull option .
    select /* keyword1 is to be the default */
        when abbrev("keyword1",option) then ...
        when abbrev("keyword2",option) then ...
    ...
    otherwise nop;
    end;

7.4.2. ABS (Absolute Value)

>>ABS(number)----------------------------------------------------------><

Returns the absolute value of number. The result has no sign and is formatted according to the current NUMERIC settings.

Here are some examples:

ABS("12.3") -> 12.3
ABS(" -0.307") -> 0.307

7.4.3. ADDRESS

>>ADDRESS()------------------------------------------------------------><

Returns the name of the environment to which commands are currently submitted. Trailing whitespace characters are removed from the result.

Here is an example:

ADDRESS() -> "CMD" /* default under Windows */
ADDRESS() -> "bash" /* default under Linux */
7.4.4. ARG (Argument)

Returns one or more arguments, or information about the arguments to a program, internal routine, or method.

If you do not specify \( n \), the number of arguments passed to the program or internal routine is returned.

If you specify only \( n \), the \( n \)th argument object is returned. If the argument object does not exist, the null string is returned. \( n \) must be a positive whole number.

If you specify \( \text{option} \), the value returned depends on the value of \( \text{option} \). The following are valid \( \text{option} \)s.

(Only the capitalized letter is needed; all characters following it are ignored.)

Array

returns a single-index array containing the arguments, starting with the \( n \)th argument. The array indexes correspond to the argument positions, so that the \( n \)th argument is at index 1, the following argument at index 2, and so on. If any arguments are omitted, their corresponding indexes are absent.

Exists

returns 1 if the \( n \)th argument exists; that is, if it was explicitly specified when the routine was called. Otherwise, it returns 0.

Normal

returns the \( n \)th argument, if it exists, or a null string.

Omitted

returns 1 if the \( n \)th argument was omitted; that is, if it was not explicitly specified when the routine was called. Otherwise, it returns 0.

Here are some examples:

```rxml
/* following "Call name;" (no arguments) */
ARG() -> 0
ARG(1) -> ""
ARG(2) -> ""
ARG(1,"e") -> 0
ARG(1,"0") -> 1
ARG(1,"a") -> .array~of()

/* following "Call name 'a', 'b';" */
ARG() -> 3
ARG(1) -> "a"
ARG(2) -> ""
ARG(3) -> "b"
ARG(n) -> "" /* for n>=4 */
ARG(1,"e") -> 1
```
Chapter 7. Functions

ARG(2,"E") -> 0
ARG(2,"O") -> 1
ARG(3,"o") -> 0
ARG(4,"o") -> 1
ARG(1,"A") -> .array~of(a, ,b)
ARG(3,"a") -> .array~of(b)

Notes:

1. The number of argument strings is the largest number \( n \) for which \( \text{ARG}(n,"e") \) returns 1 or 0 if there are no explicit argument strings. That is, it is the position of the last explicitly specified argument string.

2. Programs called as commands can have only 0 or 1 argument strings. The program has 0 argument strings if it is called with the name only and has 1 argument string if anything else (including whitespace characters) is included in the command.

3. Programs called by the RexxStart entry point can have several argument strings. (See the Open Object Rexx: Programming Guide for information about RexxStart.)

4. You can access the argument objects of a program with the USE instruction. See USE for more information.

5. You can retrieve and directly parse the argument strings of a program or internal routine with the ARG or PARSE ARG instructions.

7.4.5. B2X (Binary to Hexadecimal)

\[ \texttt{B2X(binary\_string)} \]

Returns a string, in character format, that represents \( \text{binary\_string} \) converted to hexadecimal.

The \( \text{binary\_string} \) is a string of binary (0 or 1) digits. It can be of any length. You can optionally include whitespace characters in \( \text{binary\_string} \) (at 4-digit boundaries only, not leading or trailing) to improve readability; they are ignored.

The returned string uses uppercase alphabetical characters for the values A-F, and does not include blanks or horizontal tabs.

If \( \text{binary\_string} \) is the null string, B2X returns a null string. If the number of binary digits in \( \text{binary\_string} \) is not a multiple of 4, then up to three 0 digits are added on the left before the conversion to make a total that is a multiple of 4.

Here are some examples:

\[ \text{B2X("11000011")} \quad \rightarrow \quad \text{"C3"} \]
\[ \text{B2X("10111")} \quad \rightarrow \quad \text{"17"} \]
\[ \text{B2X("101")} \quad \rightarrow \quad \text{"5"} \]
\[ \text{B2X("1 1111 0000")} \quad \rightarrow \quad \text{"1F0"} \]

You can combine B2X with the functions X2D and X2C to convert a binary number into other forms. For example:

\[ \text{X2D(B2X("10111"))} \quad \rightarrow \quad \text{"23"} \quad \text{/* decimal 23 */} \]
7.4.6. BEEP

```
>>-BEEP(frequency,duration)------------------------------------><
```

Sounds the speaker at frequency (Hertz) for duration (milliseconds). The frequency can be any whole number in the range 37 to 32767 Hertz. The duration can be any number in the range 1 to 60000 milliseconds.

This routine is most useful when called as a subroutine. A null string is returned.

**Note:** Both parameters (frequency, duration) are ignored on Windows 95 and Linux. On computers with multimedia support the function plays the default sound event. On computers without soundcard, the function plays the standard system beep (if activated).

Here is an example for Windows NT:

```rexx
/* C scale */
note.1 = 262 /* middle C */
note.2 = 294 /* D */
note.3 = 330 /* E */
note.4 = 349 /* F */
note.5 = 392 /* G */
note.6 = 440 /* A */
note.7 = 494 /* B */
note.8 = 523 /* C */

do i=1 to 8
call beep note.i,250 /* hold each note for */
/* one-quarter second */
end
```

7.4.7. BITAND (Bit by Bit AND)

```
>>-BITAND(string1--+--------------------------+--)-------------><
```

Returns a string composed of the two input strings logically ANDed, bit by bit. (The encodings of the strings are used in the logical operation.) The length of the result is the length of the longer of the two strings. If no **pad** character is provided, the AND operation stops when the shorter of the two strings is exhausted, and the unprocessed portion of the longer string is appended to the partial result. If **pad** is provided, it extends the shorter of the two strings on the right before carrying out the logical operation. The default for **string2** is the zero-length (null) string.

Here are some examples:

- `BITAND("12"x)` -> "12"x
- `BITAND("73"x,"27"x)` -> "23"x
- `BITAND("13"x,"5555"x)` -> "1155"x
- `BITAND("13"x,"5555"x,"74"x)` -> "1154"x
Chapter 7. Functions

BITAND("pQrS", "DF"x) -> "PQRS" /* ASCII */

7.4.8. BITOR (Bit by Bit OR)

Returns a string composed of the two input strings logically inclusive-ORed, bit by bit. (The encodings of the strings are used in the logical operation.) The length of the result is the length of the longer of the two strings. If no pad character is provided, the OR operation stops when the shorter of the two strings is exhausted, and the unprocessed portion of the longer string is appended to the partial result. If pad is provided, it extends the shorter of the two strings on the right before carrying out the logical operation. The default for string2 is the zero-length (null) string.

Here are some examples:

BITOR("12"x) -> "12"x
BITOR("15"x,"24"x) -> "35"x
BITOR("15"x,"2456"x) -> "3556"x
BITOR("15"x,"2456"x,"F0"x) -> "35F6"x
BITOR("1111"x,"4D"x) -> "5D5D"x
BITOR("pQrS", "20"x) -> "pqrs" /* ASCII */

7.4.9. BITXOR (Bit by Bit Exclusive OR)

Returns a string composed of the two input strings logically eXclusive-ORed, bit by bit. (The encodings of the strings are used in the logical operation.) The length of the result is the length of the longer of the two strings. If no pad character is provided, the XOR operation stops when the shorter of the two strings is exhausted, and the unprocessed portion of the longer string is appended to the partial result. If pad is provided, it extends the shorter of the two strings on the right before carrying out the logical operation. The default for string2 is the zero-length (null) string.

Here are some examples:

BITXOR("12"x) -> "12"x
BITXOR("12"x,"22"x) -> "30"x
BITXOR("1211"x,"22"x) -> "3011"x
BITXOR("1111"x,"444444"x) -> "555544"x
BITXOR("1111"x,"444444"x,"40"x) -> "555504"x
BITXOR("1111"x,"4D"x) -> "5C5C"x
BITXOR("C711"x,"222222"x," ") -> "E53302"x /* ASCII */
Chapter 7. Functions

7.4.10. C2D (Character to Decimal)

Returns the decimal value of the binary representation of string. If the result cannot be expressed as a whole number, an error results. That is, the result must not have more digits than the current setting of NUMERIC DIGITS. If you specify n, it is the length of the returned result. If you do not specify n, string is processed as an unsigned binary number.

If string is null, 0 is returned.

Here are some examples:

C2D("09"X) -> 9
C2D("81"X) -> 129
C2D("FF81"X) -> 65409
C2D(""") -> 0
C2D("a") -> 97 /* ASCII */

If you specify n, the string is taken as a signed number expressed in n characters. The number is positive if the leftmost bit is off, and negative if the leftmost bit is on. In both cases, it is converted to a whole number, which can be negative. The string is padded on the left with "00"x characters (not "sign-extended"), or truncated on the left to n characters. This padding or truncation is as though RIGHT(string, n,"00"x) had been processed. If n is 0, C2D always returns 0.

Here are some examples:

C2D("81"X,1) -> -127
C2D("81"X,2) -> 129
C2D("FF81"X,2) -> -127
C2D("FF81"X,1) -> -127
C2D("FF7"X,1) -> 127
C2D("F081"X,2) -> -3967
C2D("F081"X,1) -> -127
C2D("0031"X,0) -> 0

7.4.11. C2X (Character to Hexadecimal)

Returns a string, in character format, that represents string converted to hexadecimal. The returned string contains twice as many bytes as the input string. On an ASCII system, C2X(1) returns "31"X because the ASCII representation of the character 1 is "31"X.

The string returned uses uppercase alphabetical characters for the values A-F and does not include whitespace characters. The string can be of any length. If string is null, a null string is returned.

Here are some examples:

C2X("0123"X) -> "0123" /* "30313233"X in ASCII */
C2X("ZD8") -> "5A4438" /* "354134343338"X in ASCII */
### 7.4.12. CENTER (or CENTRE)

```plaintext
CENTER(-+-string, length--+------+--)---------------------><
   --CENTRE(-+  +-,pad-+

Returns a string of length `length` with `string` centered in it and with `pad` characters added as necessary to make up `length`. The `length` must be a positive whole number or zero. The default `pad` character is blank. If the string is longer than `length`, it is truncated at both ends to fit. If an odd number of characters is truncated or added, the right-hand end loses or gains one more character than the left-hand end.

Here are some examples:

- `CENTER(abc,7)` -> " ABC "
- `CENTER(abc,8,"-")` -> "--ABC---"
- `CENTRE("The blue sky",8)` -> "e blue s"
- `CENTRE("The blue sky",7)` -> "e blue "

**Note:** To avoid errors because of the difference between British and American spellings, this function can be called either CENTRE or CENTER.
```

### 7.4.13. CHANGESTR

```plaintext
CHANGESTR(needle,haystack,newneedle+-+---+---)------------------------><
   +-,-,count-+

Returns a copy of `haystack` in which `newneedle` replaces occurrences of `needle`. If `count` is not specified, all occurrences of `needle` are replaced. If `count` is specified, it must be a positive, whole number that gives the maximum number of occurrences to be replaced. The following defines the effect:

```rexx
result = ""
$tempx = 1
do forever
   $tempy = pos(needle, haystack, $tempx)
   if $tempy = 0 then leave
   result = result || substr(haystack, $tempx, $tempy - $tempx) || newneedle
   $tempx = $tempy + length(needle)
end
result = result || substr(haystack, $tempx)
```

Here are some examples:

- `CHANGESTR("1","101100","")` -> "000"
- `CHANGESTR("1","101100","X")` -> "X0XX00"
- `CHANGESTR("1","101100","X",1)` -> "X01100"
```
7.4.14. CHARIN (Character Input)

Returns a string of up to length characters read from the character input stream name. (To understand the input and output functions, see Input and Output Streams.) If you omit name, characters are read from STDIN, which is the default input stream. The default length is 1.

For persistent streams, a read position is maintained for each stream. Any read from the stream starts at the current read position by default. When the language processor completes reading, the read position is increased by the number of characters read. You can give a start value to specify an explicit read position. This read position must be a positive whole number and within the bounds of the stream, and must not be specified for a transient stream. A value of 1 for start refers to the first character in the stream. If start is not a positive whole number the appropriate syntax condition is raised. When the read position is past the bounds of the stream, the empty string is returned and the NOTREADY condition is raised.

If you specify a length of 0, then the read position is set to the value of start, but no characters are read and the null string is returned.

In a transient stream, if there are fewer than length characters available, the execution of the program generally stops until sufficient characters become available. If, however, it is impossible for those characters to become available because of an error or another problem, the NOTREADY condition is raised (see Errors during Input and Output) and CHARIN returns with fewer than the requested number of characters.

Here are some examples:

<table>
<thead>
<tr>
<th>Example</th>
<th>Result</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARIN(myfile,1,3)</td>
<td>&quot;MFC&quot;</td>
<td>/* the first 3 characters */</td>
</tr>
<tr>
<td>CHARIN(myfile,1,0)</td>
<td>&quot;&quot;</td>
<td>/* now at start */</td>
</tr>
<tr>
<td>CHARIN(myfile)</td>
<td>&quot;M&quot;</td>
<td>/* after last call */</td>
</tr>
<tr>
<td>CHARIN(myfile, ,2)</td>
<td>&quot;FC&quot;</td>
<td>/* after last call */</td>
</tr>
</tbody>
</table>

/* Reading from the default input (here, the keyboard) */
/* User types "abcd efg" */
CHARIN()            | "a"           | /* default is */                                                      |
                             | /* 1 character */                                                  |
CHARIN( , ,5)        | "bcd e"        |                                                                       |

Notes:

1. CHARIN returns all characters that appear in the stream, including control characters such as line feed, carriage return, and end of file.

2. When CHARIN reads from the keyboard, program execution stops until you press the Enter key.

7.4.15. CHAROUT (Character Output)
Chapter 7. Functions

+-string-+ +-start--

Returns the count of characters remaining after attempting to write string to the character output stream name. (To understand the input and output functions, see Input and Output Streams.) If you omit name, characters in string are written to STDOUT (generally the display), which is the default output stream. The string can be a null string, in which case no characters are written to the stream, and 0 is always returned.

For persistent streams, a write position is maintained for each stream. Any write to the stream starts at the current write position by default. When the language processor completes writing, the write position is increased by the number of characters written. When the stream is first opened, the write position is at the end of the stream so that calls to CHAROUT append characters to the end of the stream.

You can give a start value to specify an explicit write position for a persistent stream. This write position must be a positive whole number. A value of 1 for start refers to the first character in the stream.

You can omit the string for persistent streams. In this case, the write position is set to the value of start that was given, no characters are written to the stream, and 0 is returned. If you do not specify start or string, the stream is closed and 0 is returned.

Execution of the program usually stops until the output operation is complete.

For example, when data is sent to a printer, the system accepts the data and returns control to Rexx, even though the output data might not have been printed. Rexx considers this to be complete, even though the data has not been printed. If, however, it is impossible for all the characters to be written, the NOTREADY condition is raised (see Errors during Input and Output) and CHAROUT returns with the number of characters that could not be written (the residual count).

Here are some examples:

\[
\begin{align*}
\text{CHAROUT}(\text{myfile},"Hi") & \rightarrow 0 \quad /* \text{typically} \\
\text{CHAROUT}(\text{myfile},"Hi",5) & \rightarrow 0 \quad /* \text{typically} \\
\text{CHAROUT}(\text{myfile}, ,6) & \rightarrow 0 \quad /* \text{now at char 6} \\
\text{CHAROUT}(\text{myfile}) & \rightarrow 0 \quad /* \text{at end of stream} \\
\text{CHAROUT}(,"Hi") & \rightarrow 0 \quad /* \text{typically} \\
\text{CHAROUT}(,"Hello") & \rightarrow 2 \quad /* \text{maybe}
\end{align*}
\]

Note: This routine is often best called as a subroutine. The residual count is then available in the variable RESULT.

For example:

Call CHAROUT myfile,"Hello"
Call CHAROUT myfile,"Hi",6
Call CHAROUT myfile

7.4.16. CHARS (Characters Remaining)

+-name--

384 ooRexx Reference Version 4.0.0
Returns the total number of characters remaining in the character input stream name. The count includes any line separator characters, if these are defined for the stream. In the case of persistent streams, it is the count of characters from the current read position. (See Input and Output Streams for a discussion of Rexx input and output.) If you omit name, the number of characters available in the default input stream (STDIN) is returned.

The total number of characters remaining cannot be determined for some streams (for example, STDIN). For these streams, the CHARS function returns 1 to indicate that data is present, or 0 if no data is present. For windows devices, CHARS always returns 1.

Here are some examples:

```
CHARS(myfile)   ->  42 /* perhaps */
CHARS(nonfile) ->  0
CHARS()        ->  1 /* perhaps */
```

### 7.4.17. COMPARE

```
>>-COMPARE(string1,string2--+------+--)------------------------><
          +-,pad-+

Returns 0 if the strings string1 and string2 are identical. Otherwise, it returns the position of the first character that does not match. The shorter string is padded on the right with pad if necessary. The default pad character is a blank.

Here are some examples:

```
COMPARE(“abc”,“abc”)    ->  0
COMPARE(“abc”,“ak”)     ->  2
COMPARE(“ab ”,”ab”)     ->  0
COMPARE(“ab ”,”ab”,“ ”) ->  0
COMPARE(“ab ”,”ab”,“x”) ->  3
COMPARE(“ab-- ”,”ab”,“-”) ->  5
```

### 7.4.18. CONDITION

```
>>-CONDITION(--+--------+--)-----------------------------------><
          +-option-+

Returns the condition information associated with the current trapped condition. (See Conditions and Condition Traps for a description of condition traps.) You can request the following pieces of information:

- The name of the current trapped condition
- Any descriptive string associated with that condition
- Any condition-specific information associated with the current trapped condition
- The instruction processed as a result of the condition trap (CALL or SIGNAL)
Chapter 7. Functions

• The status of the trapped condition

In addition, you can request a condition object containing all of the preceding information.

To select the information to be returned, use the following options. (Only the capitalized letter is needed; all characters following it are ignored.)

Additional

returns any additional object information associated with the current trapped condition. See Additional Object Information for a list of possible values. If no additional object information is available or no condition has been trapped, the language processor returns the Nil object.

Condition name

returns the name of the current trapped condition. For user conditions, the returned string is a concatenation of the word USER and the user condition name, separated by a whitespace character.

Description

returns any descriptive string associated with the current trapped condition. See Descriptive Strings for the list of possible values. If no description is available or no condition has been trapped, it returns a null string.

Instruction

returns either CALL or SIGNAL, the keyword for the instruction processed when the current condition was trapped. This is the default if you omit option. If no condition has been trapped, it returns a null string.

Object

returns an object that contains all the information about the current trapped condition. See Conditions and Condition Traps for more information. If no condition has been trapped, it returns the Nil object.

Status

returns the status of the current trapped condition. This can change during processing, and is one of the following:

• ON - the condition is enabled
• OFF - the condition is disabled
• DELAY - any new occurrence of the condition is delayed or ignored

If no condition has been trapped, a null string is returned.

Here are some examples:

CONDITION() -> "CALL" /* perhaps */
CONDITION("C") -> "FAILURE"
CONDITION("I") -> "CALL"
CONDITION("D") -> "FailureTest"
CONDITION("S") -> "OFF" /* perhaps */
Note: The CONDITION function returns condition information that is saved and restored across subroutine calls (including those a CALL ON condition trap causes). Therefore, after a subroutine called with CALL ON trapname has returned, the current trapped condition reverts to the condition that was current before the CALL took place (which can be none). CONDITION returns the values it returned before the condition was trapped.

7.4.19. COPIES

>>-COPIES(string,n)--------------------------------------------><

Returns \( n \) concatenated copies of \( string \). The \( n \) must be a positive whole number or zero.

Here are some examples:

\[
\begin{align*}
\text{COPIES("abc",3)} & \rightarrow \text{"abcabcabc"} \\
\text{COPIES("abc",0)} & \rightarrow \text{""}
\end{align*}
\]

7.4.20. COUNTSTR

>>-COUNTSTR(needle,haystack)----------------------------------><

Returns a count of the occurrences of \( needle \) in \( haystack \) that do not overlap. The following defines the effect:

\[
\begin{align*}
\text{result} & = 0 \\
\text{tempx} & = \text{pos(needle,haystack)} \\
\text{do while} & \text{ temp > 0} \\
\text{result} & = \text{result} + 1 \\
\text{tempx} & = \text{pos(needle,haystack,}\text{tempx} + \text{length(needle)}) \\
\text{end}
\end{align*}
\]

Here are some examples:

\[
\begin{align*}
\text{COUNTSTR("1","101101")} & \rightarrow 4 \\
\text{COUNTSTR("KK","J0KKK0")} & \rightarrow 1
\end{align*}
\]

7.4.21. D2C (Decimal to Character)

>>-D2C(wholenumber--+----+--)----------------------------------><

\[+-,n+n\]

Returns a string, in character format, that is the ASCII representation of the decimal number. If you specify \( n \), it is the length of the final result in characters; leading "00"x (for a positive \( wholenumber \)) or "FF"x (for a negative \( wholenumber \)) characters are added to the result string as necessary. \( n \) must be a positive whole number or zero.
**Chapter 7. Functions**

*Wholenumber* must not have more digits than the current setting of NUMERIC DIGITS.

If you omit n, *wholenumber* must be a positive whole number or zero, and the result length is as needed.
Therefore, the returned result has no leading "00"x characters.

Here are some examples:

- D2C(65) -> "A" /* "41"x is an ASCII "A" */
- D2C(65,1) -> "A"
- D2C(65,2) -> " A" /* the leading character is a "00"x */
- D2C(65,5) -> " A" /* the leading characters are "00"x */
- D2C(109) -> "m" /* "6D"x is an ASCII "m" */
- D2C(-109,1) -> "δ" /* "93"x is an ASCII "δ" */
- D2C(76,2) -> " L" /* "4C"x is an ASCII "L" */
- D2C(-180,2) -> " L" /* the leading character is a "FF"x */

Implementation maximum: The output string must not have more than 250 significant characters, although it can be longer if it contains leading sign characters ("00"x and "FF"x).

### 7.4.2 D2C (Decimal to Character)

Returns a string, in character format, that represents *wholenumber*, a decimal number, converted to character. The returned string uses uppercase alphabetics for the values A-F and does not include whitespace characters.

*Wholenumber* must not have more digits than the current setting of NUMERIC DIGITS.

If you specify n, it is the length of the final result in characters. After conversion the input string is sign-extended to the required length. If the number is too big to fit n characters, it is truncated on the left. n must be a positive whole number or zero.

If you omit n, *wholenumber* must be a positive whole number or zero, and the returned result has no leading zeros.

Here are some examples:

- D2C(9) -> "9"
- D2C(129) -> "81"
- D2C(129,1) -> "1"
- D2C(129,2) -> "81"
- D2C(129,4) -> "0081"
- D2C(257,2) -> "01"
- D2C(-127,2) -> "81"
- D2C(-127,4) -> "FF81"
- D2C(12,0) -> ""

Implementation maximum: The output string must not have more than 500 significant character, although it can be longer if it contains leading sign characters (0 and F).
7.4.23. DATATYPE

Returns NUM if you specify only string and if string is a valid Rexx number that can be added to 0 without error; returns CHAR if string is not a valid number.

If you specify type, it returns 1 if string matches the type. Otherwise, it returns 0. If string is null, the function returns 0 (except when the type is X or B, for which DATATYPE returns 1 for a null string). The following are valid types. (Only the capitalized letter, or the number of the last type listed, is needed; all characters surrounding it are ignored. Note that for the hexadecimal option, you must start your string specifying the name of the option with x rather than h.)

Alphanumeric
returns 1 if string contains only characters from the ranges a-z, A-Z, and 0-9.

Binary
returns 1 if string contains only the characters 0 or 1, or whitespace. Whitespace characters can appear only between groups of 4 binary characters. It also returns 1 if string is a null string, which is a valid binary string.

Lowercase
returns 1 if string contains only characters from the range a-z.

Mixed case
returns 1 if string contains only characters from the ranges a-z and A-Z.

Number
returns 1 if DATATYPE(string) returns NUM.

Logical
returns 1 if the string is exactly "0" or "1". Otherwise it returns 0.

Symbol
returns 1 if string is a valid symbol, that is, if SYMBOL(string) does not return BAD. (See Symbols.) Note that both uppercase and lowercase alphabetics are permitted.

Uppercase
returns 1 if string contains only characters from the range A-Z.

Variable
returns 1 if string could appear on the left-hand side of an assignment without causing a SYNTAX condition.

Whole number
returns 1 if string is a Rexx whole number under the current setting of NUMERIC DIGITS.
Chapter 7. Functions

heXadecimal

returns 1 if string contains only characters from the ranges a-f, A-F, 0-9, and whitespace (as long as
the whitespace characters appear only between pairs of hexadecimal characters). It also returns 1 if
string is a null string, which is a valid hexadecimal string.

9 digits

returns 1 if DATATYPE(string,"W") returns 1 when NUMERIC DIGITS is set to 9.

Here are some examples:

| DATATYPE(" 12 ") | "NUM" |
| DATATYPE(""")   | "CHAR" |
| DATATYPE("123++") | "CHAR" |
| DATATYPE("12.3","N") | 1 |
| DATATYPE("12.3","W") | 0 |
| DATATYPE("Fred","M") | 1 |
| DATATYPE("Fred","U") | 0 |
| DATATYPE("Fred","L") | 0 |
| DATATYPE("?20K","s") | 1 |
| DATATYPE("BCd3","X") | 1 |
| DATATYPE("BC d3","X") | 1 |
| DATATYPE("1","O") | 1 |
| DATATYPE("11","O") | 0 |

Note: The DATATYPE function tests the meaning or type of characters in a string, independent of the
encoding of those characters (for example, ASCII or EBCDIC).

7.4.24. DATE

Returns, by default, the local date in the format: dd mon yyyy (day month year--for example, 13 Nov
1998), with no leading zero or blank on the day. The first three characters of the English name of the
month are used.

You can use the following options to obtain specific formats. (Only the capitalized letter is needed; all
characters following it are ignored.)
Chapter 7. Functions

Base

returns the number of complete days (that is, not including the current day) since and including the base date, 1 January 0001, in the format: 

\[ dddddd \] (no leading zeros or whitespace). The expression \( \text{DATE("B")//7} \) returns a number in the range 0-6 that corresponds to the current day of the week, where 0 is Monday and 6 is Sunday.

**Note:** The base date of 1 January 0001 is determined by extending the current Gregorian calendar backward (365 days each year, with an extra day every year that is divisible by 4 except century years that are not divisible by 400. It does not take into account any errors in the calendar system that created the Gregorian calendar originally.

Days

returns the number of days, including the current day, that have passed this year in the format \( ddd \) (no leading zeros or whitespace).

European

returns the date in the format \( dd/mm/yy \).

Full

returns the number of microseconds since 00:00:00.000000 on 1 January 0001, in the format:

\[ ddddddddddddddddd \] (no leading zeros or whitespace).

**Notes:** The base date of 1 January 0001 is determined by extending the current Gregorian calendar backward (365 days each year, with an extra day every year that is divisible by 4 except century years that are not divisible by 400. It does not take into account any errors in the calendar system that created the Gregorian calendar originally.

The value returned by \( \text{Date('F')} \) can be used to calculate the interval between any two dates. Note, however, that values returned generally contain more digits that the default NUMERIC DIGITS setting. The NUMERIC DIGITS setting should be increased to a minimum value of 18 when performing timestamp arithmetic.

Language

returns the date in an implementation- and language-dependent, or local, date format. The format is \( dd \) \( month \) \( yyyy \). The name of the month is according to the national language installed on the system. If no local date format is available, the default format is returned.

**Note:** This format is intended to be used as a whole; Rexx programs must not make any assumptions about the form or content of the returned string.
Month
returns the full English name of the current month, for example, August.

Normal
returns the date in the format dd mon yyyy. This is the default.

Ordered
returns the date in the format yy/mm/dd (suitable for sorting, for example).

Standard
returns the date in the format yyyy/mm/dd (suitable for sorting, for example).

Ticks
returns the number of seconds since 00:00:00.000000 on 1 January 1970, in the format: dddddddddddddd (no leading zeros or whitespace).

Notes: The base date of 1 January 1970 is determined by extending the current Gregorian calendar backward (365 days each year, with an extra day every year that is divisible by 4 except century years that are not divisible by 400. It does not take into account any errors in the calendar system that created the Gregorian calendar originally.

The value returned by Date('T') can be used to calculate the interval between any two dates. Note, however, that values returned generally contain more digits that the default NUMERIC DIGITS setting. The NUMERIC DIGITS setting should be increased to a minimum value of 12 when performing timestamp arithmetic.

Date('T') will return a negative number for dates prior to 1 January 1970.

Usa
returns the date in the format mm/dd/yy.

Weekday
returns the English name for the day of the week, in mixed case, for example, Tuesday.

Here are some examples, assuming today is 13 November 1996:

<table>
<thead>
<tr>
<th>DATE()</th>
<th>DATE(&quot;B&quot;)</th>
<th>DATE(&quot;D&quot;)</th>
<th>DATE(&quot;E&quot;)</th>
<th>DATE(&quot;L&quot;)</th>
<th>DATE(&quot;M&quot;)</th>
<th>DATE(&quot;N&quot;)</th>
<th>DATE(&quot;O&quot;)</th>
<th>DATE(&quot;S&quot;)</th>
<th>DATE(&quot;U&quot;)</th>
<th>DATE(&quot;W&quot;)</th>
</tr>
</thead>
</table>
Chapter 7. Functions

Note: The first call to DATE or TIME in one clause causes a time stamp to be made that is then used for all calls to these functions in that clause. Therefore, several calls to any of the DATE or TIME functions, or both, in a single expression or clause are consistent with each other.

If you specify string, DATE returns the date corresponding to string in the format option. The string must be supplied in the format option2. The option2 format must specify day, month, and year (that is, not "D", "L", "M", or "W"). The default for option2 is "N", so you need to specify option2 if string is not in the Normal format. Here are some examples:

DATE("O", "13 Feb 1923")  ->  "23/02/13"
DATE("O", "06/01/50", "U")  ->  "50/06/01"
DATE("N", "63326132161828000", "f")  ->  "23 Sep 2007"

If you specify an output separator character osep, the days, month, and year returned are separated by this character. Any nonalphanumeric character or an empty string can be used. A separator character is only valid for the formats "E", "N", "O", "S", and "U". Here are some examples:

DATE("O", "06/01/50", "U", ")  ->  "500601"
DATE("E", "02/13/96", "N", ")  ->  "13.02.96"
DATE("N", , ")  ->  "26_Mar_1998" (today)

In this way, formats can be created that are derived from their respective default format, which is the format associated with option using its default separator character. The default separator character for each of these formats is:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default separator</th>
</tr>
</thead>
<tbody>
<tr>
<td>European</td>
<td>&quot;/&quot;</td>
</tr>
<tr>
<td>Normal</td>
<td>&quot; &quot;</td>
</tr>
<tr>
<td>Ordered</td>
<td>&quot;/&quot;</td>
</tr>
<tr>
<td>Standard</td>
<td>&quot; &quot; (empty string)</td>
</tr>
<tr>
<td>Usa</td>
<td>&quot;/&quot;</td>
</tr>
</tbody>
</table>

If you specify a string containing a separator that is different from the default separator character of option2, you must also specify isep to indicate which separator character is valid for string. Basically, any date format that can be generated with any valid separator character can be used as input date string as long as its format has the generalized form specified by option2 and its separator character matches the character specified by isep.

Here are some examples:

DATE("S", "1996-11-13", "S", ")  ->  "19961113"
DATE("S", "13-Nov-1996", "S", ")  ->  "19961113"
DATE("O", "06*01*50", "U", "*")  ->  "500601"

You can determine the number of days between two dates; for example:

say date("B", "12/25/96", "U")-date("B")  " shopping days till Christmas!"
Chapter 7. Functions

If `string` does not include the century but `option` defines that the century be returned as part of the date, the century is determined depending on whether the year to be returned is within the past 50 years or the next 49 years. Assume, for example, that you specify 10/15/43 for `string` and today’s date is 10/27/1998. In this case, 1943 would be 55 years ago and 2043 would be 45 years in the future. So, 10/15/2043 would be the returned date.

**Note:** This rule is suitable for dates that are close to today’s date. However, when working with birth dates, it is recommended that you explicitly provide the century.

When requesting dates to be converted to Full format or Ticks format, a time value of "00:00:00.000000" is used for the conversion. A time stamp for a time and date combination can be created by combining a value from `Time()` for the time of day.

```plaintext
numeric digits 18 -- needed to add the timestamps
timestamp = date('f', '20072301', 'S') + time('f', '08:14:22', 'N')
```

### 7.4.25. DELSTR (Delete String)

```plaintext
>>-DELSTR(string,n--+-+---+-)--------------------------------<
                  +-,length--
```

Returns `string` after deleting the substring that begins at the `n`th character and is of `length` characters. If you omit `length`, or if `length` is greater than the number of characters from `n` to the end of `string`, the function deletes the rest of `string` (including the `n`th character). The `length` must be a positive whole number or zero. `n` must be a positive whole number. If `n` is greater than the length of `string`, the function returns `string` unchanged.

Here are some examples:

- `DELSTR("abcd",3) -> "ab"
- `DELSTR("abcde",3,2) -> "abe"
- `DELSTR("abcde",6) -> "abcde"
```

### 7.4.26. DELWORD (Delete Word)

```plaintext
>>-DELWORD(string,n--+-+---+-)--------------------------------<
                  +-,length--
```

Returns `string` after deleting the substring that starts at the `n`th word and is of `length` whitespace-delimited words. If you omit `length`, or if `length` is greater than the number of words from `n` to the end of `string`, the function deletes the rest of `string` (including the `n`th character). The `length` must be a positive whole number or zero. `n` must be a positive whole number. If `n` is greater than the number of words in `string`, the function returns `string` unchanged. The string deleted includes any whitespace characters following the final word involved but none of the whitespace preceding the first word involved.

Here are some examples:
DELWORD("Now is the time",2,2)  ->  "Now time"
DELWORD("Now is the time ",3)  ->  "Now is "
DELWORD("Now is the time",5)  ->  "Now is the time"
DELWORD("Now is the time",3,1)  ->  "Now is time"
DELWORD("Now is the time",2,2)  ->  "Now time"

Chapter 7. Functions

7.4.27. DIGITS

>>>DIGITS()--------------------------------------------------------<

Returns the current setting of NUMERIC DIGITS. See NUMERIC for more information.

Here is an example:

DIGITS()  ->  9  /* by default */

7.4.28. DIRECTORY

>>>DIRECTORY(--+--------------+--)----------------------------->

Returns the current directory, changing it to newdirectory if an argument is supplied and the named
directory exists. If newdirectory is not specified, the name of the current directory is returned. Otherwise,
an attempt is made to change to the specified newdirectory. If successful, the name of the newdirectory is
returned; if an error occurred, null is returned.

For example, the following program fragment saves the current directory and switches to a new
directory; it performs an operation there, and then returns to the former directory.

/* get current directory */
curdir = directory()
/* go play a game */
newdir = directory("/usr/games")  /* Linux type subdirectory */
if newdir = "/usr/games" then
    do
        fortune  /* tell a fortune */
    /* return to former directory */
    call directory curdir
end
else
    say "Can't find /usr/games"

7.4.29. ENDLOCAL (Linux only)

>>>ENDLOCAL()----------------------------------------------------------<
Chapter 7. Functions

Restores the directory and environment variables in effect before the last `SETLOCAL` function was run. If `ENDLOCAL` is not included in a procedure, the initial environment saved by `SETLOCAL` is restored upon exiting the procedure.

`ENDLOCAL` returns a value of 1 if the initial environment is successfully restored and a value of 0 if no `SETLOCAL` was issued or the action is otherwise unsuccessful.

Here is an example:

```plaintext
n = SETLOCAL()  /* saves the current environment */
/*
The program can now change environment variables
(with the VALUE function) and then work in the
changed environment.
*/
n = ENDLOCAL()  /* restores the initial environment */
```

For additional examples, see `SETLOCAL`.

7.4.30. `ERRORTEXT`

`ERRORTEXT(n)`

Returns the Rexx error message associated with error number `n`. `n` must be in the range 0-99. It returns the null string if `n` is in the allowed range but is not a defined Rexx error number. See Error Numbers and Messages for a complete description of error numbers and messages.

Here are some examples:

```plaintext
ERRORTEXT(16) -> "Label not found"
ERRORTEXT(60) -> ""
```

7.4.31. `FILESPEC`

`FILESPEC(option,filespec)`

Returns a selected element of `filespec`, given file specification, identified by one of the following option strings:

Drive
   The drive letter of the given `filespec`. Only available on Windows

Path
   The directory path of the given `filespec`.

Location
   The full location portion of the given `filespec`. On Windows, this will include both the Drive and Path information. On other platforms, this returns the same result as the Path option.
Chapter 7. Functions

Name
The file name of the given filespec.

Extension
The extension portion of the filespec file name.

If filespec the requested information, then the FILESPEC function returns a null string ("").

Note: Only the initial letter of option is needed.

Here are some Windows examples:

```
thisfile = "C:\WINDOWS\UTIL\SYSTEM.INI"
say FILESPEC("drive",thisfile) /* says "C:" */
say FILESPEC("path",thisfile) /* says "\WINDOWS\UTIL" */
say FILESPEC("location",thisfile) /* says "C:\WINDOWS\UTIL" */
say FILESPEC("name",thisfile) /* says "SYSTEM.INI" */
say FILESPEC("extension",thisfile) /* says "INI" */
part = "name"
say FILESPEC(part,thisfile) /* says "SYSTEM.INI" */
```

7.4.32. FORM

```
>>>FORM()------------------------------------------------------><
```

Returns the current setting of NUMERIC FORM. See NUMERIC for more information.

Here is an example:

```
FORM() -> "SCIENTIFIC" /* by default */
```

7.4.33. FORMAT

```
>>>FORMAT(number------------------------------------------------>
```

Returns number, rounded and formatted.
The number is first rounded according to standard Rexx rules, as though the operation number+0 had been carried out. The result is precisely that of this operation if you specify only number. If you specify any other options, the number is formatted as described in the following.

The before and after options describe how many characters are used for the integer and decimal parts of the result, respectively. If you omit either or both of them, the number of characters used for that part is as needed.

If before is not large enough to contain the integer part of the number (plus the sign for a negative number), an error results. If before is larger than needed for that part, the number is padded on the left with blanks. If after is not the same size as the decimal part of the number, the number is rounded (or extended with zeros) to fit. Specifying 0 causes the number to be rounded to an integer.

Here are some examples:

```
FORMAT("3",4)       ->  " 3"
FORMAT("1.73",4,0)  ->  " 2"
FORMAT("1.73",4,3)  ->  " 1.730"
FORMAT("-.76",4,1)  ->  "-0.8"
FORMAT("3.03",4)    ->  " 3.03"
FORMAT("- 12.73",,4) ->  "-12.7300"
FORMAT(" - 12.73") ->  "-12.73"
FORMAT("0.000") ->  "0"
```

The first three arguments are as described previously. In addition, expp and expt control the exponent part of the result, which, by default, is formatted according to the current NUMERIC settings of DIGITS and FORM. expp sets the number of places for the exponent part; the default is to use as many as needed (which can be zero). expt specifies when the exponential expression is used. The default is the current setting of NUMERIC DIGITS.

If expp is 0, the number is not in exponential notation. If expp is not large enough to contain the exponent, an error results.

If the number of places needed for the integer or decimal part exceeds expt or twice expt, respectively, the exponential notation is used. If expt is 0, the exponential notation is always used unless the exponent would be 0. (If expp is 0, this overrides a 0 value of expt.) If the exponent would be 0 when a nonzero expp is specified, then expp+2 blanks are supplied for the exponent part of the result. If the exponent would be 0 and expp is not specified, the number is not an exponential expression.

Here are some examples:

```
FORMAT("12345.73",,2,2)       ->  "1.234573E+04"
FORMAT("12345.73",,3,0)       ->  "1.235E+4"
FORMAT("1.234573",,3,0)       ->  "1.235"
FORMAT("12345.73",,3,6)       ->  "12345.73"
FORMAT("1234567e5",,3,0)      ->  "123456700000.000"
```

### 7.4.34. FUZZ

```>FUZZ()..........................................................<```

Returns the current setting of NUMERIC FUZZ. See NUMERIC for more information.
Here is an example:

Fuzz() -> 0 /* by default */

7.4.35. INSERT

\[\text{INSERT}\left(\text{new}, \text{target}\right)\]

Inserts the string new, padded or truncated to length length, into the string target after the n\text{th} character. The default value for n is 0, which means insertion before the beginning of the string. If specified, n and length must be positive whole numbers or zero. If n is greater than the length of the target string, the string new is padded at the beginning. The default value for length is the length of new. If length is less than the length of the string new, then INSERT truncates new to length length. The default pad character is a blank.

Here are some examples:

\[
\begin{align*}
\text{INSERT}(" ", \text{"abcdef"}, 3) & \rightarrow \text{"abc def"} \\
\text{INSERT}(\text{"123"}, \text{"abc"}, 5, 6) & \rightarrow \text{"abc 123 "} \\
\text{INSERT}(\text{"123"}, \text{"abc"}, 5, 6, \text{"+"}) & \rightarrow \text{"abc++123++"} \\
\text{INSERT}(\text{"123"}, \text{"abc"}) & \rightarrow \text{"123abc"} \\
\text{INSERT}(\text{"123"}, \text{"abc"}, 5, \text{"-"}) & \rightarrow \text{"123--abc"}
\end{align*}
\]

7.4.36. LASTPOS (Last Position)

\[\text{LASTPOS}\left(\text{needle}, \text{haystack}\right)\]

Returns the position of the last occurrence of one string, needle, in another, haystack. (See also POS (Position).) It returns 0 if needle is a null string or not found. By default, the search starts at the last character of haystack and scans backward to the beginning of the string. You can override this by specifying start, the point at which the backward scan starts and length, the range of characters to scan. The start must be a positive whole number and defaults to receiving_string\text{length} if larger than that value or omitted. The length must be a non-negative whole number and defaults to start.

Here are some examples:

\[
\begin{align*}
\text{LASTPOS}(\text{" "}, \text{"abc def ghi"}) & \rightarrow 8 \\
\text{LASTPOS}(\text{" "}, \text{"abcdefg"hi}) & \rightarrow 0 \\
\text{LASTPOS}(\text{"xy"}, \text{"efgxyz"}) & \rightarrow 4 \\
\text{LASTPOS}(\text{" "}, \text{"abc def ghi", 7}) & \rightarrow 4 \\
\text{LASTPOS}(\text{" "}, \text{"abc def ghi", 7, 3}) & \rightarrow 0
\end{align*}
\]
Chapter 7. Functions

7.4.37. LEFT

\[\text{LEFT} \left( \text{string}, \text{length} \right) \]

Returns a string of length \text{length}, containing the leftmost \text{length} characters of \text{string}. The string returned is padded with \text{pad} characters, or truncated, on the right as needed. The default \text{pad} character is a blank. \text{length} must be a positive whole number or zero. The LEFT function is exactly equivalent to:

\[\text{SUBSTR} \left( \text{string}, 1, \text{length} \right)\]

Here are some examples:

\text{LEFT}("abc d",8) \rightarrow "abc d "
\text{LEFT}("abc d",8,"." ) \rightarrow "abc d..."
\text{LEFT}("abc def",7) \rightarrow "abc de"

7.4.38. LENGTH

\[\text{LENGTH} \left( \text{string} \right)\]

Returns the length of \text{string}.

Here are some examples:

\text{LENGTH}("abcdefgh") \rightarrow 8
\text{LENGTH}("abc defg") \rightarrow 8
\text{LENGTH}(""") \rightarrow 0

7.4.39. LINEIN (Line Input)

\[\text{LINEIN} \left( \text{name}, \text{count} \right)\]

Returns \text{count} lines read from the character input stream \text{name}. The \text{count} must be 1 or 0. (To understand the input and output functions, see Input and Output Streams.) If you omit \text{name}, the line is read from the default input stream, STDIN. The default \text{count} is 1.

For persistent streams, a read position is maintained for each stream. Any read from the stream starts at the current read position by default. Under certain circumstances, a call to LINEIN returns a partial line. This can happen if the stream has already been read with the CHARIN function, and part but not all of a line (and its termination, if any) has already been read. When the language processor completes reading, the read position is moved to the beginning of the next line.

A \text{line} number may be given to set the read position to the start of a specified line. This line number must be positive and within the bounds of the stream, and must not be specified for a transient stream. The read position can be set to the beginning of the stream by giving \text{line} a value of 1.
Chapter 7. Functions

If you give a count of 0, then no characters are read and a null string is returned.

For transient streams, if a complete line is not available in the stream, then execution of the program usually stops until the line is complete. If, however, it is impossible for a line to be completed because of an error or another problem, the NOTREADY condition is raised (see Errors during Input and Output) and LINEIN returns whatever characters are available.

Here are some examples:

```rexx
LINEIN() /* Reads one line from the */ /* default input stream; */ /* usually this is an entry */ /* typed at the keyboard */
myfile = "ANYFILE.TXT"
LINEIN(myfile) -> "Current line" /* Reads one line from */ /* ANYFILE.TXT, beginning */ /* at the current read */ /* position. (If first call, */ /* file is opened and the */ /* first line is read.) */
LINEIN(myfile,1,1) -> "first line" /* Opens and reads the first */ /* line of ANYFILE.TXT (if */ /* the file is already open, */ /* reads first line); sets */ /* read position on the */ /* second line. */
LINEIN(myfile,1,0) -> "" /* No read; opens ANYFILE.TXT */ /* (if file is already open, */ /* sets the read position to */ /* the first line). */
LINEIN(myfile, ,0) -> "" /* No read; opens ANYFILE.TXT */ /* (no action if the file is */ /* already open). */
LINEIN("QUEUE:" ) -> "Queue line" /* Read a line from the queue. */ /* If the queue is empty, the */ /* program waits until a line */ /* is put on the queue. */
```

**Note:** If you want to read complete lines from the default input stream, as in a dialog with a user, use the PULL or PARSE PULL instruction.

The PARSE LINEIN instruction is also useful in certain cases. (See PARSE LINEIN.)
7.4.40. LINEOUT (Line Output)

Returns 0 if successful in writing string to the character output stream name, or 1 if an error occurs while writing the line. (To understand the input and output functions, see Input and Output Streams.) If you omit string but include line, only the write position is repositioned. If string is a null string, LINEOUT repositions the write position (if you include line) and does a carriage return. Otherwise, the stream is closed. LINEOUT adds a line-feed and a carriage-return character to the end of string.

If you omit name, the line is written to the default output stream STDOUT (usually the display).

For persistent streams, a write position is maintained for each stream. Any write to the stream starts at the current write position by default. (Under certain circumstances the characters written by a call to LINEOUT can be added to a partial line previously written to the stream with the CHAROUT routine. LINEOUT stops a line at the end of each call.) When the language processor completes writing, the write position is set to the beginning of the line following the one just written. When the stream is first opened, the write position is at the end of the stream, so that calls to LINEOUT append lines to the end of the stream.

You can specify a line number to set the write position to the start of a particular line in a persistent stream. This line number must be positive and within the bounds of the stream unless it is a binary stream (though it can specify the line number immediately after the end of the stream). A value of 1 for line refers to the first line in the stream. Note that, unlike CHAROUT, you cannot specify a position beyond the end of the stream for non-binary streams.

You can omit the string for persistent streams. If you specify line, the write position is set to the start of the line that was given, nothing is written to the stream, and the function returns 0. If you specify neither line nor string, the stream is closed. Again, the function returns 0.

Execution of the program usually stops until the output operation is effectively complete. For example, when data is sent to a printer, the system accepts the data and returns control to Rexx, even though the output data might not have been printed. Rexx considers this to be complete, even though the data has not been printed. If, however, it is impossible for a line to be written, the NOTREADY condition is raised (see Errors during Input and Output), and LINEOUT returns a result of 1, that is, the residual count of lines written.

Here are some examples:

```
LINEOUT(,"Display this") /* Writes string to the default */
/* output stream (usually, the */
/* display); returns 0 if */
/* successful */

myfile = "ANYFILE.TXT"
LINEOUT(myfile,"A new line") /* Opens the file ANYFILE.TXT and */
/* appends the string to the end. */
/* If the file is already open, */
/* the string is written at the */
/* current write position. */
/* Returns 0 if successful. */
```
Chapter 7. Functions

LINEOUT(myfile,"A new start",1) /* Opens the file (if not already */ /* open); overwrites first line */ /* with a new line. */ /* Returns 0 if successful. */

LINEOUT(myfile, ,1) /* Opens the file (if not already */ /* open). No write; sets write */ /* position at first character. */

LINEOUT(myfile) /* Closes ANYFILE.TXT */

LINEOUT is often most useful when called as a subroutine. The return value is then available in the variable RESULT. For example:

Call LINEOUT "A:rexx.bat","Shell",1
Call LINEOUT ,"Hello"

Note: If the lines are to be written to the default output stream without the possibility of error, use the SAY instruction instead.

7.4.41. LINES (Lines Remaining)

+-, Normal--
>>-LINES(-+-----------------------------+-)-----------------------><
    +name--+    +- Count--

Returns 1 if any data remains between the current read position and the end of the character input stream name. It returns 0 if no data remains. In effect, LINES reports whether a read action that CHARIN (see CHARIN (Character Input)) or LINEIN (see LINEIN (Line Input)) performs will succeed. (To understand the input and output functions, see Input and Output Streams.)

The ANSI Standard has extended this function to allow an option: "Count". If this option is used, LINES returns the actual number of complete lines remaining in the stream, irrespective of how long this operation takes.

The option "Normal" returns 1 if there is at least one complete line remaining in the file or 0 if no lines remain.

The default is "Normal".

Here are some examples:

LINES(myfile) -> 0 /* at end of the file */
LINES() -> 1 /* data remains in the */
               /* default input stream */
               /* STDIN: */

Note: The CHARS function returns the number of characters in a persistent stream or the presence of data in a transient stream.
7.4.42. LOWER

$$\text{LOWER}(\text{string}, n, \text{length})$$

Returns a new string with the characters of string beginning with character $n$ for length characters converted to lowercase. If $n$ is specified, it must be a positive whole number. If $n$ is not specified, the case conversion will start with the first character. If length is specified, it must be a non-negative whole number. If length the default is to convert the remainder of the string.

Examples:

lower("Albert Einstein") -> "albert einstein"
lower("ABCDEF", 4) -> "ABCdef"
lower("ABCDEF", 3, 2) -> "ABcdEF"

7.4.43. MAX (Maximum)

$$\text{MAX}(\text{number}_1, \text{number}_2, \ldots)$$

Returns the largest number of the list specified, formatted according to the current NUMERIC settings. You can specify any number of numbers.

Here are some examples:

MAX(12, 6, 7, 9) -> 12
MAX(17.3, 19, 17.03) -> 19
MAX(-7, -3, -4.3) -> -3
MAX(1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21) -> 21

7.4.44. MIN (Minimum)

$$\text{MIN}(\text{number}_1, \text{number}_2, \ldots)$$

Returns the smallest number of the list specified, formatted according to the current NUMERIC settings. You can specify any number of numbers.

Here are some examples:

MIN(12, 6, 7, 9) -> 6
MIN(17.3, 19, 17.03) -> 17.03
Chapter 7. Functions

MIN(-7,-3,-4.3) -> -7
MIN(21,20,19,18,17,16,15,14,13,12,11,10,9,8,7,6,5,4,3,2,1) -> 1

7.4.45. OVERLAY

>>-OVERLAY(new,target------------------------------------------->
>--+---------------------------------------+--)----------------><
+[-,--+---+--+-------------------------+-+
+-n-+ +-,--+--------+--+------+-+
+-length-+ +-,pad-+

Returns the string target, which, starting at the nth character, is overlaid with the string new, padded or truncated to length length. The overlay may extend beyond the end of the original target string. If you specify length, it must be a positive whole number or zero. The default value for length is the length of new. If n is greater than the length of the target string, the string new is padded at the beginning. The default pad character is a blank, and the default value for n is 1. If you specify n, it must be a positive whole number.

Here are some examples:

OVERLAY(" ","abcdef",3) -> "ab def"
OVERLAY(" ","abcdef",3,2) -> "ab. ef"
OVERLAY("qq","abcd") -> "qqcd"
OVERLAY("qq","abcd",4) -> "abcqq"
OVERLAY("123","abc",5,6,"+") -> "abc+123+++"

7.4.46. POS (Position)

>>-POS(needle,haystack--+---------------------------+--)--------------------------><
+[-,--+-------+--+---------+-+
+-start-+ +-,length-+

Returns the position of one string, needle, in another, haystack. (See also LASTPOS (Last Position).) It returns 0 if needle is a null string or not found or if start is greater than the length of haystack. By default, the search starts at the first character of the receiving string (that is, the value of start is 1), and continues to the end of the string. You can override this by specifying start, the point at which the search starts, and length, the bounding limit for the search. If specified, start must be a positive whole number and length must be a non-negative whole number.

Here are some examples:

POS("day","Saturday") -> 6
POS("x","abc def ghi") -> 0
POS(" ","abc def ghi") -> 4
POS(" ","abc def ghi",5) -> 8
POS(" ","abc def ghi",5,3) -> 0
7.4.47. QUALIFY

\[\text{QUALIFY(name)}\]

Returns the a fully qualified file name for \textit{name}. Qualifying merely expands the file name into a name that includes directory information. The file does not need to exist to generate the full name.

7.4.48. QUEUED

\[\text{QUEUED()}\]

Returns the number of lines remaining in the external data queue when the function is called. (See Input and Output Streams for a discussion of Rexx input and output.)

Here is an example:

\[\text{QUEUED()} \rightarrow 5 \quad /* \text{Perhaps} */\]

7.4.49. RANDOM

\[\text{RANDOM}(-\text{+max}--)\]

Returns a quasi-random whole number in the range \textit{min} to \textit{max} inclusive. If you specify \textit{max} or \textit{min}, \textit{max} minus \textit{min} cannot exceed 999999999. \textit{min} and \textit{max} default to 0 and 999, respectively. To start a repeatable sequence of results, use a specific \textit{seed} as the third argument, as described in Note 1. This \textit{seed} must be a positive whole number from 0 to 999999999.

Here are some examples:

\[
\begin{align*}
\text{RANDOM()} & \rightarrow 305 \\
\text{RANDOM(5,8)} & \rightarrow 7 \\
\text{RANDOM(2)} & \rightarrow 0 /* 0 to 2 */ \\
\text{RANDOM(, ,1983)} & \rightarrow 123 /* reproducible */ \\
\text{RANDOM(\text{-5, 5})} & \rightarrow -3
\end{align*}
\]

Notes:

1. To obtain a predictable sequence of quasi-random numbers, use \text{RANDOM} a number of times, but specify a \textit{seed} only the first time. For example, to simulate 40 throws of a 6-sided, unbiased die:

\[
\begin{align*}
\text{sequence} = \text{RANDOM(1,6,12345)} /* \text{any number would} */ \\
& /* \text{do for a seed} */ \\
\text{do 39} \\
\text{sequence} = \text{sequence} \text{RANDOM(1,6)} \\
\text{end} \\
\text{say sequence}
\end{align*}
\]
The numbers are generated mathematically, using the initial seed, so that as far as possible they appear to be random. Running the program again produces the same sequence; using a different initial seed almost certainly produces a different sequence. If you do not supply a seed, the first time RANDOM is called, an arbitrary seed is used. Hence, your program usually gives different results each time it is run.

2. The random number generator is global for an entire program; the current seed is not saved across internal routine calls.

### 7.4.50. REVERSE

```language=rxml
>>-REVERSE(string)--------------------------------------------------------------------->
```

Returns string reversed.

Here are some examples:

- `REVERSE("ABc." )` -> ".cBA"
- `REVERSE("XYZ ")` -> " ZYX"

### 7.4.51. RIGHT

```language=rxml
>>-RIGHT(string,length--+-...)------------------------------------------------------>
```

Returns a string of length length containing the rightmost length characters of string. The string returned is padded with pad character, or truncated, on the left as needed. The default pad character is a blank. The length must be a positive whole number or zero.

Here are some examples:

- `RIGHT("abc d",8)` -> " abc d"
- `RIGHT("abc def",5)` -> "c def"
- `RIGHT("12",5,"0")` -> "00012"

### 7.4.52. RXFUNCADD

```language=rxml
>>-RXFUNCADD(name,module---...)------------------------------------------------------>
```

Registers the function, making it available to Rexx procedures. The module is the name of an external library where the native function is located. In some environments, such as Unix-based systems, the library name is case sensitive. The procedure is the name of the exported procedure inside of module. If procedure is not specified, it defaults to name. The procedure is generally case-sensitive. RxFuncAdd will attempt to resolve the procedure address using the name as specified and if that attempt fails, will retry using an uppercased name.
Chapter 7. Functions

A return value 0 signifies successful registration and that the registered function has been located in the specified module. A return value 1 signifies that the function could not be resolved.

\[
\text{rxfuncadd("SysCls", "rexxutil", "SysCls")} \rightarrow 0 \quad \text{/* if SysCls can be located */} \\
\rightarrow 1 \quad \text{/* if SysCls can not be located */}
\]

7.4.53. RXFUNCDROP

\[
\text{rxfunclddrop(name)}--------------------------------------------><
\]

Removes (deregisters) the function \text{name} from the list of available functions. A zero return value signifies successful removal.

\[
\text{rxfunclddrop("SysLoadFuncs")} \rightarrow 0 \quad \text{/* if successfully removed */}
\]

7.4.54. RXFUNCQUERY

\[
\text{rxfuncquery(name)}-------------------------------------------><
\]

Queries the list of available functions for the function \text{name}. It returns a value of 0 if the function is registered, and a value of 1 if it is not.

\[
\text{rxfuncquery("SysLoadFuncs")} \rightarrow 0 \quad \text{/* if registered */}
\]

7.4.55. RXQUEUE

\[
\text{rxqueue(-+-"Create"-+------------+-+-)----------------------><}\\
\mid \text{+-,queuename+-} \\
\mid \text{+-"Delete",queuename------} \\
\mid \text{+-"Get"-------------------} \\
\mid \text{+-"Set",newqueuename------}
\]

Creates and deletes external data queues. It also sets and queries their names.

"Create"

creates a queue with the name \text{queue name} if you specify \text{queue name} and if no queue of that name exists already. You must not use SESSION as a \text{queue name}. If you specify no \text{queue name}, then the language processor provides a name. The name of the queue is returned in either case.

The maximum length of \text{queue name} can be 1024 characters.

Many queues can exist at the same time, and most systems have sufficient resources available to support several hundred queues at a time. If a queue with the specified name exists already, a queue is still created with a name assigned by the language processor. The assigned name is then returned to you.
"Delete"
deletes the named queue. It returns 0 if successful or a nonzero number if an error occurs. Possible
return values are:

0
Queue has been deleted.

5
Not a valid queue name or tried to delete queue named "SESSION".

9
Specified queue does not exist.

10
Queue is busy; wait is active.

12
A memory failure has occurred.

1002
Failure in memory manager.

"Get"
returns the name of the queue currently in use.

"Set"
sets the name of the current queue to newqueue and returns the previously active queue name.

The first parameter determines the function. Only the first character of the first parameter is significant.
The parameter can be entered in any case. The syntax for a valid queue name is the same as for a valid
Rexx symbol.

The second parameter specified for Create, Set, and Delete must follow the same syntax rules as the
Rexx variable names. There is no connection, however, between queue names and variable names. A
program can have a variable and a queue with the same name. The actual name of the queue is the
uppercase value of the name requested.

Named queues prevent different Rexx programs that are running in a single session from interfering with
each other. They allow Rexx programs running in different sessions to synchronize execution and pass
data. LINEIN("QUEUE:") is especially useful because the calling program stops running until another
program places a line on the queue.

/* default queue */
rxqueue("Get") -> "SESSION"

/* assuming FRED does not already exist */
rxqueue("Create", "Fred") -> "FRED"

/* assuming SESSION had been active */
rxqueue("Set", "Fred") -> "SESSION"
7.4.56. SETLOCAL (Linux only)

>>-SETLOCAL()--------------------------------------------------><

Saves the current working directory and the current values of the environment variables that are local to
the current process.

For example, SETLOCAL can be used to save the current environment before changing selected settings
with the VALUE function (see VALUE. To restore the directory and environment, use the ENDOLOCAL
function (see ENDOLOCAL.

SETLOCAL returns a value of 1 if the initial directory and environment are successfully saved and a
value of 0 if unsuccessful. If SETLOCAL is not followed by an ENDOLOCAL function in a procedure,
the initial environment saved by SETLOCAL is restored upon exiting the procedure.

Here is an example:

/* Current path is "user/bin" */
n = SETLOCAL() /* saves all environment settings */
/* Now use the VALUE function to change the PATH variable */
p = VALUE("Path","home/user/bin"."ENVIRONMENT")
/* Programs in directory home/user/bin can now be run */
n = ENDOLOCAL() /* restores initial environment including */
    /* the changed PATH variable, which is */
    /* "user/bin" */

7.4.57. SIGN

>>-SIGN(number)--------------------------------------------------><

Returns a number that indicates the sign of number. The number is first rounded according to standard
Rexx rules, as though the operation number+0 had been carried out. It returns -1 if number is less than 0,
0 if it is 0, and 1 if it is greater than 0.

Here are some examples:

SIGN("12.3") -> 1
SIGN(" -0.307") -> -1
SIGN(0.0) -> 0

7.4.58. SOURCeline

>>-SOURCeline(----+-++)--------------------------------------------------><

+-n+-
Returns the line number of the final line in the program if you omit \( n \). If you specify \( n \), returns the \( n \)th line in the program if available at the time of execution. Otherwise, it returns a null string. If specified, \( n \) must be a positive whole number and must not exceed the number that a call to SOURCELINE with no arguments returns.

If the Rexx program is in tokenized form the this function raises an error for all attempts to retrieve a line of the program.

Here are some examples:

\[
\begin{align*}
\text{SOURCELINE()} & \rightarrow 10 \\
\text{SOURCELINE(1)} & \rightarrow /* This is a 10-line Rexx program */
\end{align*}
\]

### 7.4.59. SPACE

\[
\text{SPACE(string, } n \text{, pad)}
\]

Returns the whitespace-delimited words in \( string \) with \( n \) pad characters between each word. If you specify \( n \), it must be a positive whole number or zero. If it is 0, all whitespace characters are removed. Leading and trailing whitespace characters are always removed. The default for \( n \) is 1, and the default pad character is a blank.

Here are some examples:

\[
\begin{align*}
\text{SPACE("abc def ")} & \rightarrow "abc def" \\
\text{SPACE(" abc def",3)} & \rightarrow "abc def" \\
\text{SPACE("abc def ",1)} & \rightarrow "abc def" \\
\text{SPACE("abc def ",0)} & \rightarrow "abcdef" \\
\text{SPACE("abc def ",2,"+")} & \rightarrow "abc++def"
\end{align*}
\]

### 7.4.60. STREAM

\[
\text{STREAM(name, state)}
\]

Returns a string describing the state of, or the result of an operation upon, the character stream \( name \). The result may depend on characteristics of the stream that you have specified in other uses of the STREAM function. (To understand the input and output functions, see Input and Output Streams.) This function requests information on the state of an input or output stream or carries out some specific operation on the stream.

The first argument, \( name \), specifies the stream to be accessed. The second argument can be one of the following strings that describe the action to be carried out. (Only the capitalized letter is needed; all characters following it are ignored.)
Command

an operation (specified by the stream_command given as the third argument) is applied to the selected input or output stream. The string that is returned depends on the command performed and can be a null string. The possible input strings for the stream_command argument are described later.

Description

returns any descriptive string associated with the current state of the specified stream. It is identical to the State operation, except that the returned string is followed by a colon and, if available, additional information about the ERROR or NOTREADY states.

State

returns a string that indicates the current state of the specified stream. This is the default operation. The returned strings are as described in STATE.

Note: The state (and operation) of an input or output stream is global to a Rexx program; it is not saved and restored across internal function and subroutine calls (including those calls that a CALL ON condition trap causes).

7.4.60.1. Stream Commands

The following stream commands are used to:

• Open a stream for reading, writing, or both.
• Close a stream at the end of an operation.
• Position the read or write position within a persistent stream (for example, a file).
• Get information about a stream (its existence, size, and last edit date).

The streamcommand argument must be used when--and only when--you select the operation C (command). The syntax is:

```
>>>-STREAM(name,"C",streamcommand)------------------------------><
```

In this form, the STREAM function itself returns a string corresponding to the given streamcommand if the command is successful. If the command is unsuccessful, STREAM returns an error message string in the same form as the D (Description) operation supplies.

For most error conditions, the additional information is in the form of a numeric return code. This return code is the value of ERRNO that is set whenever one of the file system primitives returns with a -1.

7.4.60.1.1. Command Strings

The argument streamcommand can be any expression that the language processor evaluates to a command string that corresponds to the following diagram:

```
+-BOTH--| Write Options |---+
```
Chapter 7. Functions

OPEN opens the named stream. The default for OPEN is to open the stream for both reading and writing data, for example, "OPEN BOTH".

The STREAM function itself returns a description string similar to the one that the $D$ option provides, for example, "READY:" if the named stream is successfully opened, or "ERROR:2" if the named stream is not found.

The following is a description of the options for OPEN:

READ

opens the stream for reading only.
Chapter 7. Functions

WRITE

opens the stream for writing only.

BOTH

opens the stream for both reading and writing. (This is the default.) Separate read and write pointers are maintained.

APPEND

positions the write pointer at the end of the stream. The write pointer cannot be moved anywhere within the extent of the file as it existed when the file was opened.

REPLACE

sets the write pointer to the beginning of the stream and truncates the file. In other words, this option deletes all data that was in the stream when opened.

SHARED

Enables another process to work with the stream in a shared mode. This mode must be compatible with the shared mode (SHARED, SHAREREAD, or SHAREWRITE) used by the process that opened the stream.

SHAREREAD

Enables another process to read the stream in a shared mode.

SHAREWRITE

Enables another process to write the stream in a shared mode.

NOBUFFER

turns off buffering of the stream. Thus, all data written to the stream is flushed immediately to the operating system for writing. This option can severely affect output performance. Therefore, use it only when data integrity is a concern, or to force interleaved output to a stream to appear in the exact order in which it was written.

BINARY

causes the stream to be opened in binary mode. This means that line end characters are ignored and treated as another byte of data. This is intended to force file operations that are compatible with other Rexx language processors that run on record-based systems, or to process binary data using the line operations.

Note: Specifying the BINARY option for a stream that does not exist but is opened for writing also requires the RECLENGTH option to be specified. Omitting the RECLENGTH option in this case raises an error condition.
Chapter 7. Functions

RECLENGTH length

allows the specification of an exact length for each line in a stream. This allows line operations on binary-mode streams to operate on individual fixed-length records. Without this option, line operations on binary-mode files operate on the entire file (for example, as if the RECLENGTH option were specified with a length equal to that of the file). length must be 1 or greater.

Examples:

stream(strout,"c","open")
stream(strout,"c","open write")
stream(strinp,"c","open read")
stream(strinp,"c","open read shared")

CLOSE

closes the named stream. The STREAM function itself returns READY: if the named stream is successfully closed, or an appropriate error message. If an attempt is made to close an unopened file, STREAM returns a null string ("").

Example:

stream("STRM.TXT","c","close")

FLUSH

forces any data currently buffered for writing to be written to this stream.

SEEK offset

sets the read or write position within a persistent stream. If the stream is opened for both reading and writing and no SEEK option is specified, both the read and write positions are set.

Note: See Input and Output Streams for a discussion of read and write positions in a persistent stream.

To use this command, the named stream must first be opened with the OPEN stream command or implicitly with an input or output operation. One of the following characters can precede the offset number:

= explicitly specifies the offset from the beginning of the stream. This is the default if no prefix is supplied. Line Offset=1 means the beginning of stream.

< specifies offset from the end of the stream.

+ specifies offset forward from the current read or write position.
Chapter 7. Functions

- specifies offset backward from the current read or write position.

The STREAM function itself returns the new position in the stream if the read or write position is successfully located or an appropriate error message otherwise.

The following is a description of the options for SEEK:

**READ**
specifies that the read position is to be set by this command.

**WRITE**
specifies that the write position is to be set by this command.

**CHAR**
specifies that the positioning is to be done in terms of characters. This is the default.

**LINE**
specifies that the positioning is to be done in terms of lines. For non-binary streams, this is an operation that can take a long time to complete, because, in most cases, the file must be scanned from the top to count line-end characters. However, for binary streams with a specified record length, this results in a simple multiplication of the new resulting line number by the record length, and then a simple character positioning. See Line versus Character Positioning for a detailed discussion of this issue.

**Note:** If you do line positioning in a file open only for writing, you receive an error message.

**Examples:**

```
stream(name,"c","seek =2 read")
stream(name,"c","seek +15 read")
stream(name,"c","seek -? write line")
fromend = 125
stream(name,"c","seek <"fromend read")
```

**POSITION**
is a synonym for SEEK.

7.4.60.1.2. QUERY Stream Commands

Used with these stream commands, the STREAM function returns specific information about a stream. Except for QUERY HANDLE and QUERY POSITION, the language processor returns the query information even if the stream is not open. The language processor returns UNKNOWN for QUERY STREAMTYPE and the null string for nonexistent streams.

Note that technically although a directory is persistent, it is not a stream. If the directory exists, the date / time queries return the time stamp of the directory, QUERY SIZE returns 0, and QUERY STREAMTYPE returns UNKNOWN. The other commands return the null string.
QUERY DATETIME
returns the date and time stamps of a stream in US format. This is included for compatibility with OS/2®.
stream("..ile.txt","c","query datetime")
A sample output might be:
11-12-98 03:29:12

QUERY EXISTS
returns the full path specification of the named stream, if it exists, or a null string.
stream("..ile.txt","c","query exists")
A sample output might be:
c:\data\file.txt

QUERY HANDLE
returns the handle associated with the open stream.
stream("..ile.txt","c","query handle")
A sample output might be:
3

QUERY POSITION
returns the current read or write position for the stream, as qualified by the following options:

READ
returns the current read position.

WRITE
returns the current write position.

Note: If the stream is open for both reading and writing, the default is to return the read position. Otherwise, it returns the appropriate position by default.

CHAR
returns the position in terms of characters. This is the default.

LINE
returns the position in terms of lines. For non-binary streams, this operation can take a long time to complete, because the language processor starts tracking the current line number if not already doing so. Thus, it might require a scan of the stream from the top to count line-end characters. See Line versus Character Positioning for a detailed discussion of this issue.
stream("myfile","c","query position write")
Chapter 7. Functions

A sample output might be:

247

SYS

returns the operating-system stream position in terms of characters.

QUERY SIZE

returns the size, in bytes, of a persistent stream.

stream("..ile.txt","c","query size")

A sample output might be:

1305

QUERY STREAMTYPE

returns a string indicating whether the stream is PERSISTENT, TRANSIENT, or UNKNOWN.

QUERY TIMESTAMP

returns the date and time stamps of a stream in an international format. This is the preferred method of getting the date and time because it provides the full 4-digit year.

stream("..ile.txt","c","query timestamp")

A sample output might be:

1998-11-12 03:29:12

7.4.61. STRIP

>>>-STRIP(string--+--------------------------+--)---------------><

+++,-+--------------------------+++---+

+-option+- +-char+-

Returns string with leading characters, trailing characters, or both, removed, based on the option you specify. The following are valid options. (Only the capitalized letter is needed; all characters following it are ignored.)

Both

removes both leading and trailing characters from string. This is the default.

Leading

removes leading characters from string.

Trailing

removes trailing characters from string.
Chapter 7. Functions

The third argument, char, specifies the character to be removed, and the default is to remove all whitespace characters. If you specify char, it must be exactly one character long.

Here are some examples:

STRIP("  ab c  ") -> "ab c"
STRIP("  ab c  ","L") -> "ab c "
STRIP("  ab c  ","t") -> "  ab c"
STRIP("12.7000", ,0) -> "12.7"
STRIP("0012.700", ,0) -> "12.7"

7.4.62. SUBSTR (Substring)

```rxml
>>>SUBSTR(string,n+-+----------------------------------++<
   +-+-+---------------------------------++
   +length-+   +-.pad-++
```

Returns the substring of string that begins at the nth character and is of length length, padded with pad if necessary. n must be a positive whole number. If n is greater than LENGTH(string), only pad characters are returned.

If you omit length, the rest of the string is returned. The default pad character is a blank.

Here are some examples:

SUBSTR("abc",2) -> "bc"
SUBSTR("abc",2,4) -> "bc "
SUBSTR("abc",2,6,".") -> "bc...."

**Note:** In some situations the positional (numeric) patterns of parsing templates are more convenient for selecting substrings, especially if more than one substring is to be extracted from a string. See also LEFT and RIGHT.

7.4.63. SUBWORD

```rxml
>>-SUBWORD(string,n+-+-----------------------)<
   +-+,length-++
```

Returns the substring of string that starts at the nth word, and is up to length whitespace-delimited words. n must be a positive whole number. If you omit length, it defaults to the number of remaining words in string. The returned string never has leading or trailing whitespace, but includes all whitespace characters between the selected words.

Here are some examples:

SUBWORD("Now is the time",2,2) -> "is the"
SUBWORD("Now is the time",3) -> "the time"
SUBWORD("Now is the time",5) -> ""

ooRexx Reference Version 4.0.0
7.4.64. SYMBOL

```symbol(name)```

Returns the state of the symbol named by `name`. It returns BAD if `name` is not a valid Rexx symbol. It returns VAR if it is the name of a variable, that is, a symbol that has been assigned a value. Otherwise, it returns LIT, indicating that it is either a constant symbol or a symbol that has not yet been assigned a value, that is, a literal.

As with symbols in Rexx expressions, lowercase characters in `name` are translated to uppercase and substitution in a compound name occurs if possible.

**Note:** You should specify `name` as a literal string, or it should be derived from an expression, to prevent substitution before it is passed to the function.

Here are some examples:

```rxml
/* following: Drop A.3; J=3 */
SYMBOL("J") -> "VAR"
SYMBOL(J) -> "LIT" /* has tested "3" */
SYMBOL("a.j") -> "LIT" /* has tested A.3 */
SYMBOL(2) -> "LIT" /* a constant symbol */
SYMBOL("*") -> "BAD" /* not a valid symbol */
```

7.4.65. TIME

```time(--option-+-string--+-option2--)```

Returns the local time in the 24-hour clock format hh:mm:ss (hours, minutes, and seconds) by default, for example, 04:41:37.

You can use the following options to obtain alternative formats, or to gain access to the elapsed-time clock. (Only the capitalized letter is needed; all characters following it are ignored.)

Civil

returns the time in Civil format hh:mmxx. The hours can take the values 1 through 12, and the minutes the values 00 through 59. The minutes are followed immediately by the letters am or pm. This distinguishes times in the morning (12 midnight through 11:59 a.m.--appearing as 12:00 am through 11:59 am) from noon and afternoon (12 noon through 11:59 p.m.--appearing as 12:00 pm through 11:59 pm). The hour has no leading zero. The minute field shows the current minute (rather than the nearest minute) for consistency with other TIME results.

Elapsed

returns sssssssss.uuuuuu, the number of seconds and microseconds since the elapsed-time clock (described later) was started or reset. The returned number has no leading zeros or whitespace, and
the setting of NUMERIC DIGITS does not affect it. The number has always four trailing zeros in
the decimal portion.

The language processor calculates elapsed time by subtracting the time at which the elapsed-time
clock was started or reset from the current time. It is possible to change the system time clock while
the system is running. This means that the calculated elapsed time value might not be a true elapsed
time. If the time is changed so that the system time is earlier than when the Rexx elapsed-time clock
was started (so that the elapsed time would appear negative), the language processor raises an error
and disables the elapsed-time clock. To restart the elapsed-time clock, trap the error through
SIGNAL ON SYNTAX.

The clock can also be changed by programs on the system. Many LAN-attached programs
synchronize the system time clock with the system time clock of the server during startup. This
causes the Rexx elapsed time function to be unreliable during LAN initialization.

**Full**

returns the number of microseconds since 00:00:00.000000 on 1 January 0001, in the format:
```plaintext
dddddddddddddd (no leading zeros or whitespace).
```

**Notes:** The base date of 1 January 0001 is determined by extending the current Gregorian
calendar backward (365 days each year, with an extra day every year that is divisible by 4
except century years that are not divisible by 400. It does not take into account any errors in the
calendar system that created the Gregorian calendar originally.

The value returned by Time('F') can be used to calculate the interval between any two times.
Note, however, that values returned generally contain more digits that the default NUMERIC
DIGITS setting. The NUMERIC DIGITS setting should be increased to a minimum value of 18
when performing timestamp arithmetic.

**Hours**

returns up to two characters giving the number of hours since midnight in the format hh (no leading
zeros or whitespace, except for a result of 0).

**Long**

returns time in the format hh:mm:ss.uuuuuu (where uuuuu are microseconds).

**Minutes**

returns up to four characters giving the number of minutes since midnight in the format mmmm (no
leading zeros or whitespace, except for a result of 0).

**Normal**

returns the time in the default format hh:mm:ss. The hours can have the values 00 through 23, and
minutes and seconds, 00 through 59. There are always two digits. Any fractions of seconds are
ignored (times are never rounded). This is the default.
Chapter 7. Functions

Offset
returns the offset of the local time from UTC in microseconds. The offset value will be negative for
timezones west of the Prime Meridian and positive for timezones east of Prime Meridian. The local
time('F') value can be converted to UTC by adding the time('O') value.

Reset
returns sssssssss.uuuuuu, the number of seconds and microseconds since the elapsed-time clock
described later) was started or reset and also resets the elapsed-time clock to zero. The returned
number has no leading zeros or whitespace, and the setting of NUMERIC DIGITS does not affect
it. The number always has four trailing zeros in the decimal portion.
See the Elapsed option for more information on resetting the system time clock.

Seconds
returns up to five characters giving the number of seconds since midnight in the format ssss (no
leading zeros or whitespace, except for a result of 0).

Ticks
returns the number of seconds since 00:00:00.000000 on 1 January 1970, in the format:
ddddddddddddd (no leading zeros or whitespace).

Notes: The base date of 1 January 1970 is determined by extending the current Gregorian
calendar backward (365 days each year, with an extra day every year that is divisible by 4
except century years that are not divisible by 400. It does not take into account any errors in the
calendar system that created the Gregorian calendar originally.
The value returned by Time('T') can be used to calculate the interval between any two times.
Note, however, that values returned generally contain more digits that the default NUMERIC
DIGITS setting. The NUMERIC DIGITS setting should be increased to a minimum value of 12
when performing timestamp arithmetic.
Time('T') will return a negative number for dates prior to 1 January 1970.

Here are some examples, assuming that the time is 4:54 p.m.:

<table>
<thead>
<tr>
<th>Function</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME()</td>
<td>&quot;16:54:22&quot;</td>
</tr>
<tr>
<td>TIME(&quot;C&quot;)</td>
<td>&quot;4:54pm&quot;</td>
</tr>
<tr>
<td>TIME(&quot;H&quot;)</td>
<td>&quot;16&quot;</td>
</tr>
<tr>
<td>TIME(&quot;L&quot;)</td>
<td>&quot;16:54:22.120000&quot; /* Perhaps */</td>
</tr>
<tr>
<td>TIME(&quot;M&quot;)</td>
<td>&quot;1014&quot; /* 54 + 60*16 */</td>
</tr>
<tr>
<td>TIME(&quot;N&quot;)</td>
<td>&quot;16:54:22&quot;</td>
</tr>
<tr>
<td>TIME(&quot;S&quot;)</td>
<td>&quot;60862&quot; /* 22 + 60*(54+60*16) */</td>
</tr>
</tbody>
</table>

The elapsed-time clock:
You can use the TIME function to measure real (elapsed) time intervals. On the first call in a program to
TIME("E") or TIME("R"), the elapsed-time clock is started, and either call returns 0. From then on, calls to
TIME("E") and TIME("R") return the elapsed time since that first call or since the last call to TIME("R").
The clock is saved across internal routine calls, which means that an internal routine inherits the time
clock that its caller started. Any timing the caller is doing is not affected, even if an internal routine resets
the clock. An example of the elapsed-time clock:

\[
\begin{align*}
time("E") & \rightarrow 0 \quad /\text{ The first call }/ \\
& \quad /\text{ pause of one second here }/ \\
time("E") & \rightarrow 1.020000 \quad /\text{ or thereabouts }/ \\
& \quad /\text{ pause of one second here }/ \\
time("R") & \rightarrow 2.030000 \quad /\text{ or thereabouts }/ \\
& \quad /\text{ pause of one second here }/ \\
time("R") & \rightarrow 1.050000 \quad /\text{ or thereabouts }/ \\
\end{align*}
\]

Note: The elapsed-time clock is synchronized with the other calls to TIME and DATE, so several
calls to the elapsed-time clock in a single clause always return the same result. For this reason, the
interval between two usual TIME/DATETIME results can be calculated exactly using the elapsed-time
clock.

If you specify \textit{string}, TIME returns the time corresponding to \textit{string} in the format \textit{option}. The \textit{string}
must be supplied in the format \textit{option2}. The default for \textit{option2} is "N". So you need to specify \textit{option2}
only if \textit{string} is not in the Normal format. \textit{option2} must specify the current time, for example, not "E" or
"R". Here are some examples:

\[
\begin{align*}
time("C","11:27:21") & \rightarrow 11:27:00 \quad /\text{am }/ \\
time("N","11:27am","C") & \rightarrow 11:27:00 \\
time("N", "63326132161828000", "F") & \rightarrow 08:16:01 \\
\end{align*}
\]

You can determine the difference between two times; for example:

If \text{TIME("M","5:00pm","C")-TIME("M")<=0}
then say "Time to go home"
else say "Keep working"

The \text{TIME} returned is the earliest time consistent with \textit{string}. For example, if the result requires
components that are not specified in the source format, then those components of the result are zero. If
the source has components that the result does not need, then those components of the source are ignored.

When requesting times be converted to Full or Ticks format, a date value of 1 January 0001 is used for
the conversion. A time stamp for a time and date combination can be created by combining a value from
\text{Date("F")} for the time of day.

\[
\text{numeric digits 18 -- needed to add the timestamps} \\
\text{timestamp = date('f', '20072301', 'S') + time('f', '08:14:22', 'N')} \\
\]

\textbf{Implementation maximum:} If the number of seconds in the elapsed time exceeds nine digits
(equivalent to over 31.6 years), an error results.

\section*{7.4.66. TRACE}

\texttt{>>-TRACE(this----)}---------------------------------------><
Chapter 7. Functions

+-option-+

Returns trace actions currently in effect and, optionally, alters the setting.

If you specify option, it selects the trace setting. It must be the valid prefix `?`, one of the alphabetic character options associated with the TRACE instruction (that is, starting with `A`, `C`, `E`, `F`, `I`, `L`, `N`, `O`, or `R`), or both. (See the TRACE instruction in Alphabetic Character (Word) Options for full details.)

Unlike the TRACE instruction, the TRACE function alters the trace action even if interactive debugging is active. Also unlike the TRACE instruction, option cannot be a number.

Here are some examples:

```
TRACE() -> "?R" /* maybe */
TRACE("O") -> "?R" /* also sets tracing off */
TRACE("?I") -> "O" /* now in interactive debugging */
```

7.4.67. TRANSLATE

```
>>-TRANSLATE(string--------------------------------------------->
>+--+--------------------------------------------+--)--------------------------------+-><
|+-tableo-+ |+-tablei-+ +-+,pad-+ +-pos-+ +-+,length-|
```

Returns string with each character translated to another character or unchanged. You can also use this function to reorder the characters in string.

The output table is tableo and the input translation table is tablei. TRANSLATE searches tablei for each character in string. If the character is found, the corresponding character in tableo is used in the result string; if there are duplicates in tablei, the first (leftmost) occurrence is used. If the character is not found, the original character in string is used. The result string is always the same length as string.

The tables can be of any length. If you specify neither table and omit pad, string is simply translated to uppercase (that is, lowercase `a-z` to uppercase `A-Z`), but, if you include pad, the language processor translates the entire string to `XRANGE("00"x,"FF"x)`, and `tableo` defaults to the null string and is padded with `pad` or truncated as necessary. The default pad is a blank.

pos is the position of the first character of the translated range. The default starting position is 1. length is the range of characters to be translated. If omitted, length remainder of the string from the starting position to the end is used.

Here are some examples:

```
TRANSLATE("abcdef") -> "ABCDEF"
TRANSLATE("abcdef", , , 2, 3) -> "aBCDef"
TRANSLATE("abcdef", "12", "ec") -> "ab2d1f"
TRANSLATE("abcdef", "12", "abcd", ".") -> "12.ef"
TRANSLATE("APQRV", , "PR") -> "A Q V"
TRANSLATE("APQRV", XRANGE("00"X, "Q")) -> "APQ "
TRANSLATE("4123", "abcd", "1234") -> "dabc"
TRANSLATE("4123", "abcd", "1234", , 2, 2) -> "4ab1"
```
Note: The last example shows how to use the TRANSLATE function to reorder the characters in a string. The last character of any four-character string specified as the second argument is moved to the beginning of the string.

### 7.4.68. TRUNC (Truncate)

```
TRUNC(number) +----------------+-------------------------------------><
        +-,n-+
```

Returns the integer part of number and n decimal places. The default n is 0 and returns an integer with no decimal point. If you specify n, it must be a positive whole number or zero. The number is rounded according to standard Rexx rules, as though the operation number+0 had been carried out. Then it is truncated to n decimal places or trailing zeros are added to reach the specified length. The result is never in exponential form. If there are no nonzero digits in the result, any minus sign is removed.

Here are some examples:

- `TRUNC(12.3)` -> 12
- `TRUNC(127.09782,3)` -> 127.097
- `TRUNC(127.1,3)` -> 127.100
- `TRUNC(127,2)` -> 127.00

Note: The number is rounded according to the current setting of NUMERIC DIGITS, if necessary, before the function processes it.

### 7.4.69. UPPER

```
UPPER(string) +----------------+-------------------------------------><
        +--,--+-----+--+-----------+-+
        +--n--+ +--,length--+
```

Returns a new string with the characters of string beginning with character n for length characters converted to uppercase. If n is specified, it must be a positive whole number. If n is not specified, the case conversion will start with the first character. If length is specified, it must be a non-negative whole number. If length the default is to convert the remainder of the string.

Examples:

- `upper("Albert Einstein")` -> "ALBERT EINSTEIN"
- `upper("abcdef", 4)` -> "abcDEF"
- `upper("abcdef", 3, 2)` -> "abCDef"
Chapter 7. Functions

7.4.70. USERID

```
>>-USERID()----------------------------------------------------><
```

The return value is the active user identification.

7.4.71. VALUE

```
>>-VALUE(name--+--------------------------------+--)-----------><
+-,--+----------+--+-----------+-+
|-,selector-|
```

Returns the value of the symbol that `name` (often constructed dynamically) represents and optionally assigns a new value to it. By default, VALUE refers to the current Rexx-variables environment, but other, external collections of variables can be selected. If you use the function to refer to Rexx variables, `name` must be a valid Rexx symbol. (You can confirm this by using the SYMBOL function.) Lowercase characters in `name` are translated to uppercase for the local environment. For the global environment lowercase characters are not translated because the global environment supports mixed-case identifiers. Substitution in a compound name (see Compound Symbols) occurs if possible.

If you specify `newvalue`, the named variable is assigned this new value. This does not affect the result returned; that is, the function returns the value of `name` as it was before the new assignment.

Here are some examples:

```rxml
/* After: Drop A3; A33=7; K=3; fred="K"; list.5="Hi" */
VALUE("a"k) -> "A3" /* looks up A3 */
VALUE("a"k||k) -> "7"
VALUE("fred") -> "K" /* looks up FRED */
VALUE(fred) -> "3" /* looks up K */
VALUE(fred,5) -> "3" /* looks up K and */
 /* then sets K=5 */
VALUE(fred) -> "5" /* looks up K */
VALUE("LIST."k) -> "Hi" /* looks up LIST.5 */
```

To use VALUE to manipulate environment variables, `selector` must be the string "ENVIRONMENT" or an expression that evaluates to "ENVIRONMENT". In this case, the variable `name` need not be a valid Rexx symbol. Environment variables set by VALUE are not kept after program termination.

**Restriction:** The values assigned to the variables must not contain any character that is a hexadecimal zero ("00"X). For example:

Call VALUE "MYVAR", "FIRST" || "00"X || "SECOND", "ENVIRONMENT"

sets MYVAR to "FIRST", truncating "00"x and "SECOND".

Here are some more examples:

```rxml
/* Given that an external variable FRED has a value of 4 */
share = "ENVIRONMENT"
say VALUE("fred",7,share) /* says "4" and assigns */
 /* FRED a new value of 7 */
```
say VALUE("fred", ,share) /* says "7" */

/* Accessing and changing Windows environment entries given that */
/* PATH=C:\EDIT\DOCS; */

env = "ENVIRONMENT"
new = "C:\EDIT\DOCS;"

say value("PATH",new,env) /* says "C:\WINDOWS" (perhaps) */
/* and sets PATH = "C:\EDIT\DOCS;" */

say value("PATH", ,env) /* says "C:\EDIT\DOCS;" */

To delete an environment variable use the Nil object as the newvalue. To delete the environment variable "MYVAR" specify: value("MYVAR", .NIL, "ENVIRONMENT"). If you specify an empty string as the newvalue like in value("MYVAR", "ENVIRONMENT") the value of the external environment variable is set to an empty string which on Windows and *nix is not the same as deleting the environment variable.

A selector called "WSHENGINE" is also available to the VALUE function when a Rexx script is run in a Windows Script Host scripting context (running via cscript, wscript or as embedded code in HTML for the Microsoft Internet Explorer). The only currently supported value is "NAMEDITEMS". Calling VALUE with these parameters returns an array with the names of the named items that were added at script start.

Example:

myArray = VALUE("NAMEDITEMS", ,"WSHENGINE")

The value NAMEDITEMS is read-only, writing to it is prohibited.

Object Rexx scripts running via the scripting engine (in WSH context) can now call the default method of an object as a function call with the object name.

Example:

The SESSION object of ASP (Active Server Pages) has the default method VALUE. The usual (and recommended) way of using the SESSION object would be to use

SESSION~VALUE("key","value").

Because VALUE is the default method, a function call

SESSION("key","value")
SESSION~VALUE("key","value").

causes an invocation of VALUE with the given arguments. For objects that have the name of a Rexx function, an explicit call to the default method must be made, because Rexx functions have priority over this implicit method invocation mechanism.

Note: In contrast to OS/2, the Windows and *nix environments are unchanged after program termination.

You can use the VALUE function to return a value to the global environment directory. To do so, omit newvalue and specify selector as the null string. The language processor sends the message name (without arguments) to the current environment object. The environment returns the object identified by
name. If there is no such object, it returns, by default, the string name with an added initial period (an environment symbol--see Environment Symbols).

Here are some examples:

```rexx
/* Assume the environment name MYNAME identifies the string "Simon" */
name = value("MYNAME", ",") /* Sends MYNAME message to the environment */
name = .myname /* Same as previous instruction */
say "Hello," name /* Produces: "Hello, Simon" */
/* Assume the environment name NONAME does not exist. */
name = value("NONAME", ",") /* Sends NONAME message to the environment */
say "Hello," name /* Produces: "Hello, .NONAME" */
```

You can use the VALUE function to change a value in the Rexx environment directory. Include a newvalue and specify selector as the null string. The language processor sends the message name (with = appended) and the single argument newvalue to the current environment object. After receiving this message, the environment identifies the object newvalue by the name name.

Here is an example:

```rexx
name = value("MYNAME","David","") /* Sends "MYNAME=("David") message */
/* to the environment. */
/* You could also use: */
/* call value "MYNAME","David","" */
say "Hello," .myname /* Produces: "Hello, David" */
```

Notes:

1. If the VALUE function refers to an uninitialized Rexx variable, the default value of the variable is always returned. The NOVALUE condition is not raised because a reference to an external collection of variables never raises NOVALUE.

2. The VALUE function is used when a variable contains the name of another variable, or when a name is constructed dynamically. If you specify name as a single literal string and omit newvalue and selector, the symbol is a constant and the string between the quotation marks can usually replace the whole function call. For example, fred=VALUE("k"); is identical with the assignment fred=k;, unless the NOVALUE condition is trapped. See Conditions and Condition Traps.

### 7.4.72. VAR

```rexx
>>-VAR(name)---------------------------------------------------><
```

Returns 1 if name is the name of a variable, that is, a symbol that has been assigned a value), or 0.

Here are some examples:

```rexx
/* Following: DROP A.3; J=3 */
VAR("J")   -> 1
VAR(J)     -> 0  /* has tested "3" */
VAR("a.j") -> 0  /* has tested "A.3" */
VAR(2)     -> 0  /* a constant symbol */
VAR("*")  -> 0  /* an invalid symbol */
```
7.4.73. VERIFY

\[
\text{VERIFY}(\text{string}, \text{reference}) \rightarrow \text{number}
\]

Returns a number that, by default, indicates whether \text{string} is composed only of characters from \text{reference}. It returns 0 if all characters in \text{string} are in \text{reference}, or returns the position of the first character in \text{string} that is not in \text{reference}.

The \text{option} can be either \text{Nomatch} (the default) or \text{Match}. (Only the capitalized and highlighted letter is needed. All characters following it are ignored, and it can be in uppercase or lowercase characters.) If you specify \text{Match}, the function returns the position of the first character in the \text{string} that is in \text{reference}, or returns 0 if none of the characters are found.

The default for \text{start} is 1; thus, the search starts at the first character of \text{string}. You can override this by specifying a different \text{start} point, which must be a positive whole number.

The default for \text{length} is the length of the string from \text{start} to the end of the string. Thus, the search proceeds to the end of the receiving string. You can override this by specifying a different \text{length}, which must be a non-negative whole number.

If \text{string} is null, the function returns 0, regardless of the value of the third argument. Similarly, if \text{start} is greater than \text{LENGTH(string)}, the function returns 0. If \text{reference} is null, the function returns 0 if you specify \text{Match}; otherwise, the function returns the \text{start} value.

Here are some examples:

\begin{verbatim}
VERIFY("123","1234567890") -> 0
VERIFY("1Z3","1234567890") -> 2
VERIFY("AB4T","1234567890") -> 1
VERIFY("AB4T","1234567890","M") -> 3
VERIFY("AB4T","1234567890","N") -> 1
VERIFY("1P3Q4","1234567890",3) -> 4
VERIFY("123","",2) -> 2
VERIFY("ABCDE","",3) -> 3
VERIFY("ABCDEF","ABC",4) -> 6
VERIFY("ABCDEF","ADEF",2,3) -> 4
VERIFY("ABCDEF","ADE",2,3) -> 4
\end{verbatim}

7.4.74. WORD

\[
\text{WORD}(\text{string}, n) \rightarrow \text{string}
\]

Returns the \text{n}th whitespace-delimited word in \text{string} or returns the null string if less than \text{n} words are in \text{string}. \text{n} must be a positive whole number. This function is equal to \text{SUBWORD(string, n,1)}.

Here are some examples:

\begin{verbatim}
WORD("Now is the time",3) -> "the"
WORD("Now is the time",5) -> ""
\end{verbatim}
Chapter 7. Functions

7.4.75. WORDINDEX

WORDINDEX(string,n) ---

Returns the position of the first character in the nth whitespace-delimited word in string or returns 0 if less than n words are in string. n must be a positive whole number.

Here are some examples:

WORDINDEX("Now is the time",3) -> 8
WORDINDEX("Now is the time",6) -> 0

7.4.76. WORDLENGTH

WORDLENGTH(string,n) ---

Returns the length of the nth whitespace-delimited word in the string or returns 0 if less than n words are in the string. n must be a positive whole number.

Here are some examples:

WORDLENGTH("Now is the time",2) -> 2
WORDLENGTH("Now comes the time",2) -> 5
WORDLENGTH("Now is the time",6) -> 0

7.4.77. WORDPOS (Word Position)

WORDPOS(phrase,string) ---

Returns the word number of the first word of phrase found in string or returns 0 if phrase contains no words or if phrase is not found. Several whitespace characters between words in either phrase or string are treated as a single blank for the comparison, but otherwise the words must match exactly.

By default, the search starts at the first word in string. You can override this by specifying start (which must be positive), the word at which to start the search.

Here are some examples:

WORDPOS("the","now is the time") -> 3
WORDPOS("The","now is the time") -> 0
WORDPOS("is the","now is the time") -> 2
WORDPOS("is the","now is the time") -> 2
WORDPOS("is time ","now is the time") -> 0
WORDPOS("be","To be or not to be") -> 2
WORDPOS("be","To be or not to be",3) -> 6
7.4.78. WORDS

>>-WORDS(string)----------------------------------------------><

Returns the number of whitespace-delimited words in string.

Here are some examples:

WORDS("Now is the time") -> 4
WORDS(" ") -> 0

7.4.79. X2B (Hexadecimal to Binary)

>>-X2B(hexstring)----------------------------------------------><

Returns a string, in character format, that represents hexstring converted to binary. The hexstring is a string of hexadecimal characters. It can be of any length. Each hexadecimal character is converted to a string of 4 binary digits. You can optionally include whitespace characters in hexstring (at byte boundaries only, not leading or trailing) to improve readability; they are ignored.

The returned string has a length that is a multiple of 4, and does not include any whitespace.

If hexstring is null, the function returns a null string.

Here are some examples:

X2B("C3") -> "11000011"
X2B("7") -> "0111"
X2B("1 C1") -> "000111000001"

You can combine X2B with the functions D2X and C2X to convert numbers or character strings into binary form.

Here are some examples:

X2B(C2X("C3")) -> "11000011"
X2B(D2X("129")) -> "10000001"
X2B(D2X("12")) -> "1100"

7.4.80. X2C (Hexadecimal to Character)

>>-X2C(hexstring)----------------------------------------------><

Returns a string, in character format, that represents hexstring converted to character. The returned string has half as many bytes as the original hexstring. hexstring can be of any length. If necessary, it is padded with a leading zero to make an even number of hexadecimal digits.

You can optionally include whitespace characters in hexstring (at byte boundaries only, not leading or trailing) to improve readability; they are ignored.

If hexstring is null, the function returns a null string.
Chapter 7. Functions

Here are some examples:

```
X2C("4865 6c6c 6f") -> "Hello" /* ASCII */
X2C("3732 73") -> "72s" /* ASCII */
```

### 7.4.81. X2D (Hexadecimal to Decimal)

```
X2D(hexstring) +-,n--
```

Returns the decimal representation of `hexstring`. The `hexstring` is a string of hexadecimal characters. If the result cannot be expressed as a whole number, an error occurs. That is, the result must not have more digits than the current setting of NUMERIC DIGITS.

You can optionally include whitespace characters in `hexstring` (at byte boundaries only, not leading or trailing) to aid readability; they are ignored.

If `hexstring` is null, the function returns 0.

If you do not specify `n`, the `hexstring` is processed as an unsigned binary number.

Here are some examples:

```
X2D("0E") -> 14
X2D("81") -> 129
X2D("F81") -> 3969
X2D("FF81") -> 65409
X2D("46 30"X) -> 240 /* ASCII */
X2D("66 30"X) -> 240 /* ASCII */
```

If you specify `n`, the string is taken as a signed number expressed in `n` hexadecimal digits. If the leftmost bit is off, then the number is positive; otherwise, it is a negative number. In both cases it is converted to a whole number, which can be negative. If `n` is 0, the function returns 0.

If necessary, `hexstring` is padded on the left with 0 characters (not "sign-extended"), or truncated on the left to `n` characters.

Here are some examples:

```
X2D("81",2) -> -127
X2D("81",4) -> 129
X2D("F081",4) -> -3967
X2D("F081",3) -> 129
X2D("F081",2) -> -127
X2D("F081",1) -> 1
X2D("0031",0) -> 0
```

### 7.4.82. XRANGE (Hexadecimal Range)

```
XRANGE(start+, end++)
```

Returns the range of `start` and `end`, both inclusive, as hexadecimal numbers.

Here are some examples:

```
XRANGE(7, E) -> 7-14
XRANGE(7, F) -> 7-15
XRANGE(80, 81) -> 80-81
XRANGE(80, 82) -> 80-82
XRANGE(80, 83) -> 80-83
```

If `end` is null, it is treated as all 1s, and the result is the range of `start` to all 1s.

If `start` is null, it is treated as all 0s, and the result is the range of all 0s to `end`.

If `start` is greater than `end`, the function returns an error.

If `start` and `end` have different lengths, the function returns an error.

If `start` is greater than `end`, the function returns an error.
Chapter 7. Functions

Returns a string of all valid 1-byte encodings (in ascending order) between and including the values \textit{start} and \textit{end}. The default value for \textit{start} is "00"x, and the default value for \textit{end} is "FF"x. If \textit{start} is greater than \textit{end}, the values wrap from "FF"x to "00"x. If specified, \textit{start} and \textit{end} must be single characters.

Here are some examples:

\begin{verbatim}
XRANGE("a","f")  ->  "abcdef"
XRANGE("03"x,"07"x)  ->  "0304050607"x
XRANGE(,"04"x)  ->  "0001020304"x
XRANGE("FE"x,"02"x)  ->  "FEFF000102"x
XRANGE("i","j")  ->  "ij"  /* ASCII */
\end{verbatim}
Chapter 7. Functions
Chapter 8. Rexx Utilities (RexxUtil)

RexxUtil is a Dynamic Link Library (DLL) package for Windows and *nix platforms; the package contains external Rexx functions. These functions:

- Manipulate operating system files and directories
- Manipulate Windows classes and objects
- Perform text screen input and output

All of the RexxUtil functions are registered by the ooRexx interpreter on startup so there is no need to register the functions either individually or via the SysLoadFuncs function.

8.1. A Note on Error Codes

On Windows, some of the REXXUTIL functions return operating system error codes on failure. The SysGetErrorText() function can be used retrieve a description of system error code. In addition, the meaning of these error return codes can be looked up in the Windows Operating System documentation provided by Microsoft.

The documentation is called the MSDN Library. The library is provided online for anyone to access. Pus, since May 2006, Microsoft has also provided the ISO images for the library free of charge. Anyone can download the ISOS, burn them to a CD, and install the library locally on their system.

The information below is provided to help the Rexx programmer locate the MSDN Library, if they would like to. All things on the Internet change. The URLs listed here are accurate at the time of this writing.

The online MSDN Library is currently located at:
A direct link to the section on the System Error codes is:

A Google search of MSDN Library will turn up the section on the error codes. A Google search of MSDN “System Error Codes” will turn up the section on the error codes.

Directions to the downloadable ISO images of the MSDN Library have been posted on this blog entry:

A Google search using: "Rob Caron" General Downloads MSDN Library should also turn up the blog entry.

8.2. List of Rexx Utility Functions

The following table lists all of the REXXUTIL functions and the platforms on which they are available.

Table 8-1. Rexx Utility Library Functions

### 8.3. RxMessageBox (Windows only)

```plaintext
>>-RxMessageBox(text-------------------------------------------->
|+-RxMessageBox(text-------------------------------------------->+
| |++-title++ ++,--------------------------+-+ |
| |++-button++ ++,icon++ |
```

Displays a Windows message box.

RxMessageBox returns the selected message box push button. Possible values are:

1. The OK push button was pressed
2. The CANCEL push button was pressed
3. The ABORT push button was pressed
4. The RETRY push button was pressed
5. The IGNORE push button was pressed
The YES push button was pressed

The NO push button was pressed

If a message box has a "CANCEL" button, the function returns the 2 value if either the ESC key is pressed or the "CANCEL" button is selected. If the message box has no "CANCEL" button, pressing ESC has no effect.

text
The message box text.

title
The message box title. The default title is "Error!".

button
The message box push button style. The allowed styles are:

"NONE"
No icon is displayed.

"OK"
A single OK push button.

"OKCANCEL"
An OK push button and a CANCEL push button.

"RETRYCANCEL"
A RETRY push button and a CANCEL push button.

"ABORTRETRYIGNORE"
An ABORT push button, a RETRY push button and an IGNORE push button.

"YESNO"
A YES push button and a NO push button.

"YESNOCANCEL"
A YES push button, a NO push button and a CANCEL push button.

The default push button style is OK.
icon

The message box icon style. The allowed styles are:

"HAND"
    A hand icon is displayed.

"QUESTION"
    A question mark icon is displayed.

"EXCLAMATION"
    An exclamation point icon is displayed.

"ASTERISK"
    An asterisk icon is displayed.

"INFORMATION"
    An information icon is displayed.

"STOP"
    A stop icon is displayed.

"QUERY"
    A query icon is displayed.

"WARNING"
    A warning icon is displayed.

"ERROR"
    An error icon is displayed.

Example:

/* Give option to quit         */
if RxMessageBox("Shall we continue", , "YesNo", "Question") = 7
Then Exit                /* quit option given, exit       */

8.4. RxWinExec (Windows only)

>>-RxWinExec(-cmdline--+------------+--)-----------------------><
+-,--cmdshow-+

Starts (executes) the application as specified in cmdline.

Parameters:
**cmdline**

A string containing a file name and optional parameters for the application to be executed. If the name of the executable file in *cmdline* does not contain a directory path, RxWinExec searches for the executable file in this sequence:

1

The directory from which Object Rexx was loaded.

2

The current directory.

3

The Windows system directory.

4

The Windows directory.

5

The directories listed in the PATH environment variable.

**cmdshow**

Specifies how a Windows-based application window is to be shown. For a non-Windows-based application, the PIF file, if any, for the application determines the window state.

**SHOWNORMAL**

Activates and displays a window.

**SHOWNOACTIVATE**

Displays the window while the current active window remains active.

**SHOWMINNOACTIVE**

Displays the window as a minimized window, the current active window remains active.

**SHOWMINIMIZED**

Activates the window and displays it as a minimized window.

**SHOWMAXIMIZED**

Activates the window and displays it as a maximized window.

**HIDE**

Hides the window and activates another window.

**MINIMIZE**

Minimizes the specified window and activates the next top-level window in the Z order.
Return codes:
If the application is started successfully, the process id (PID) is returned. If an error occurs the returned value is less than 32.

Error return codes correspond to a Windows System Error code. If the Windown system error code is greater than 32 it is negated. This is to prevent confusion between a legitimate error code and a PID.

Some common error returns for this function are as follows.

2
The specified file was not found.

3
The specified path was not found.

11
The EXE file is invalid.

-53
The network path is invalid.

8.5. SysAddRexxMacro

 Adds a routine to the Rexx macrospace. SysAddRexxMacro returns the RexxAddMacro return code.

Parameters:

name
The name of the function added to the macrospace.

file
The file containing the Rexx program.

order
The macrospace search order. The order can be "B" (Before) or "A" (After).

8.6. SysBootDrive (Windows only)

 Returns the drive used to boot Windows, for example, "C:".
8.7. SysClearRexxMacroSpace

>>>-SysClearRexxMacroSpace()------------------------------------><

Clears the Rexx macrospace. SysClearRexxMacroSpace returns the RexxClearMacroSpace return code.

8.8. SysCloseEventSem

>>>-SysCloseEventSem(handle)------------------------------------><

Closes an event semaphore.

Parameter:

handle

A handle returned from a previous SysCreateEventSem or SysOpenEventSem call.

Return codes:

0

No errors.

Other

An error occurred. On Windows, a Windows System Error code is returned. This may be one of the following, but could be others.

6

Invalid handle.

102

Error semaphore busy.

8.9. SysCloseMutexSem

>>>-SysCloseMutexSem(handle)------------------------------------><

Closes a mutex semaphore.

Parameter:

handle

A handle returned from a previous SysCreateMutexSem call.

Return codes:
Chapter 8. Rexx Utilities (RexxUtil)

0

No errors.

Other

An error occurred. On Windows, a Windows System Error code is returned. This may be one of the following, but could be others.

6

Invalid handle.

102

Error semaphore busy.

8.10. SysCls

>>>-SysCls()----------------------------------------------------><

Clears the screen.

Example:

/* Code */
call SysCls

8.11. SysCreateEventSem

>>>-SysCreateEventSem(-+------+--+--------------+-)-------------><

Creates or opens an event semaphore. It returns an event semaphore handle that can be used with SysCloseEventSem, SysOpenEventSem, SysResetEventSem, SysPostEventSem, and SysWaitEventSem. SysCreateEventSem returns a null string (""") if the semaphore cannot be created or opened.

Parameters:

name

The optional event semaphore name. If you omit name, SysCreateEventSem creates an unnamed, shared event semaphore. If you specify name, SysCreateEventSem opens the semaphore if the semaphore has already been created. A semaphore name can be MAX_PATH long, and can contain any character except the backslash (\) path-separator character. Semaphore names are case-sensitive.

manual_reset

A flag to indicate that the event semaphore must be reset manually by SysResetEventSem. If this parameter is omitted, the event semaphore is reset automatically by SysWaitEventSem.
8.12. **SysCreateMutexSem**

`>>-SysCreateMutexSem(-+------+-)-------------------------------><
 +--name--+

Creates or opens a mutex semaphore. Returns a mutex semaphore handle that can be used with `SysCloseMutexSem`, `SysRequestMutexSem`, and `SysReleaseMutexSem`. `SysCreateMutexSem` returns a null string ("") if the semaphore cannot be created or opened.

**Parameter:**

`name`

The optional mutex semaphore name. If you omit `name`, `SysCreateMutexSem` creates an unnamed, shared mutex semaphore. If you specify `name`, `SysCreateMutexSem` opens the semaphore if the mutex has already been created. The semaphore names cannot be longer than 63 characters. Semaphore names are case-sensitive.

8.13. **SysCreatePipe (Unix only)**

`>>-SysCreatePipe()---------------------------------------------><

Creates an unnamed pipe.

**Returns:**

Returns a string like "handle handle" where the first handle is for read and the second handle for write.

8.14. **SysCurPos (Windows only)**

`>>-SysCurPos(-+------------+-)---------------------------------><
 +-row,column-+

Returns the cursor position in the form `row col` and optionally moves the cursor to a new location.

**Parameters:**

`row`

The row to move to.

`col`

The column to move to.

**Note:** Position (0,0) is the upper left corner.

You can call `SysCurPos` without a column and row position to obtain the cursor position without moving the cursor.
Example:

```rexx
call SysCls
parse value SysCurPos() with row col
say "Cursor position is "row", "col
```

/* Output */
Cursor position is 0, 0

8.15. **SysCurState (Windows only)**

```rexx
>>>SysCurState(state)------------------------------------------><
```

Hides or displays the cursor.

**Parameter:**

`state`

The new cursor state. Allowed states are:

"ON"

  Display the cursor

"OFF"

  Hide the cursor

8.16. **SysDriveInfo (Windows only)**

```rexx
>>>SysDriveInfo(drive)-----------------------------------------><
```

Returns drive information in the form: `drive: free total label`

**drive:**

  is the drive letter identifier.

**free**

  is the drive unused space.

**total**

  is the total size of the drive.
Chapter 8. Rexx Utilities (RexxUtil)

label

is the drive label.

If the drive is not accessible, then SysDriveInfo returns "".

Parameter:

drive

The drive of interest, "C:".

Example:

/* Code */
say "Disk="SysDriveInfo("C:"
/* Output */
Disk=C: 33392640 83687424 TRIGGER_C

8.17. SysDriveMap (Windows only)

>>>-SysDriveMap(+-+-------+-+------+-)---------------------------><
    +drive+++-,opt+-

Returns a string listing accessible drives (separated by blanks) in the form: C: D: ....

Parameters:

drive

The first drive letter of the drive map. The default is "C:"

opt

The drivemap option. This can be:

"USED"

returns the drives that are accessible or in use, including all local and remote drives. This is the default.

"FREE"

returns drives that are free or not in use.

"LOCAL"

returns only local drives.

"REMOTE"

returns only remote drives, such as redirected LAN resources or installable file system (IFS) attached drives.
Chapter 8. Rexx Utilities (RexxUtil)

"REMOVABLE"
returns removable drives.

"CDROM"
returns CD-ROM drives.

"RAMDISK"
returns drives assigned from RAM.

Example:
/* Code */
say "Used drives include:"
say SysDriveMap("C:", "USED")
/* Output */
Used drives include:
C: D: E: F: W:

8.18. SysDropFuncs

>>>-SysDropFuncs---------------------------------------------><

From ooRexx 4.0.0 and on this function does nothing.

8.19. SysDropRexxMacro

>>>-SysDropRexxMacro(name)--------------------------------------><

Removes a routine from the Rexx macro space. SysDropRexxMacro returns the RexxDropMacro return code.

Parameter:

name

The name of the function removed from the macro space.

8.20. SysDumpVariables

>>>-SysDumpVariables---------------------------------------------><

Dumps all variables in the current scope either to the specified file filename (new data is appended) or to STDOUT if you omit filename. The format of the data is, with one variable per line:

Name=MYVAR, Value="This is the content of MYVAR"
Parameter:

filename

The name of the file to which variables are appended. The dump is written to STDOUT if you omit this parameter.

Return codes:

0

Dump completed successfully.

-1

Dump failed.

Example:

Call SysDumpVariables "MyVars.Lst" /* append vars to file */
Call SysDumpVariables /* list vars on STDOUT */

8.21. SysFileCopy (Windows only)

Copies a file from one location to another. Wildcard file specifications are not allowed.

Parameter:

source

The path/name of the file to be copied.

target

The path/name of the target location where the file is to be copied.

Return codes:

0

File copied successfully.

Other

A Windows System Error code.

Example:

/* Code */
call SysFileCopy "c:\temp\myfile.txt", "d:\myfolder"
8.22. SysFileDelete

Deletes a file. SysFileDelete does not support wildcard file specifications.

Parameter:

`file`

The name of the file to be deleted.

Return codes:

0

File deleted successfully.

Other

An error occurred. On Windows, a Windows System Error code is returned. This may be one of the following, but could be others.

2

File not found.

3

Path not found.

5

Access denied or busy.

26

Not DOS disk.

32

Sharing violation.

36

Sharing buffer exceeded.

87

Does not exist.

206

File name exceeds range error.

Example:

/* Code */
parse arg InputFile OutputFile
call SysFileDelete OutputFile /* unconditionally erase output file */

8.23. SysFileExists

>>>-SysFileExists(filename)----------------------------------------<

Checks for the existence of a file. This function does not support wildcard specifications. Returns true if any file system entity with the given name exists. In particular, this will return true for both regular files and directories.

Parameters:

filename

The name of the file to check for the existence of.

Returns:

0

The file does not exist.

1

The file exists.

Example:

if SysFileExists(InputFile) then say "File Exists!"
else say "File does not exist."

8.24. SysFileMove (Windows only)

>>>-SysFileMove(source, target)---------------------------------><

Moves a file from one location to another. Wildcard file specifications are not allowed.

Parameter:

source

The path/name of the file to be moved.

target

The path of the target location where the file is to be moved. The target must contain a path component.

Return codes:
Chapter 8. Rexx Utilities (RexxUtil)

0

File copied successfully.

Other

On failure, a Windows System Error code is returned.

Example:

/* Code */
call SysFileMove "c:\temp\myfile.txt", "d:\myfolder"

8.25. SysFileSearch

>>>SysFileSearch(target,file,stem,...)<
+-,options+

Finds all file lines containing the target string and returns the file lines in a Rexx stem variable collection.

Parameters:

target

The target search string.

file

The searched file.

stem

The result stem variable name. SysFileSearch sets Rexx variable stem.0 to the number of lines returned and stores the individual lines in variables stem.1 to stem.n.

options

Any combination of the following one-character options:

"C"

Conducts a case-sensitive search.

"N"

Returns the file line numbers.

The default is a case-insensitive search without line numbers.

Return codes:

0

Successful.
Chapter 8. Rexx Utilities (RexxUtil)

2
Not enough memory.

3
Error opening file.

Example:

/* Find DEVICE statements in CONFIG.SYS */
call SysFileSearch "DEVICE", "C:\CONFIG.SYS", "file."
do i=1 to file.0
say file.i
end

/* Output */
DEVICE=C:\SB16\DRV\CTSB16.SYS /UNIT=0 /BLASTER=A:240 I:5 D:1 H:5
DEVICE=C:\SB16\DRV\CTMMSYS.SYS
rem **** DOS SCSI CDROM device drivers ***
DEVICE=C:\SCSI\ASPI8DOS.SYS /D
DEVICE=C:\SCSI\ASPICD.SYS /D:ASPICD0
rem **** IDE CDROM device drivers
DEVICE=C:\DOS\HIMEM.SYS
DEVICE=C:\SBCD\DRV\SBIDE.SYS /V /D:MSCD001 /P:1f0,14
DEVICE=C:\DOS\SETVER.EXE
DEVICE=C:\WINDOWS\SMARTDRV.EXE /DOUBLE_BUFFER
DEVICE=C:\WINDOWS\IFSHLP.SYS

/* Find DEVICE statements in CONFIG.SYS (along with */
/* line numbers) */
call SysFileSearch "DEVICE", "C:\CONFIG.SYS", "file.", "N"
do i=1 to file.0
say file.i
end

/* Output */
1 DEVICE=C:\SB16\DRV\CTSB16.SYS /UNIT=0 /BLASTER=A:240 I:5 D:1 H:5
2 DEVICE=C:\SB16\DRV\CTMMSYS.SYS
4 rem **** DOS SCSI CDROM device drivers ***
5 DEVICE=C:\SCSI\ASPI8DOS.SYS /D
6 DEVICE=C:\SCSI\ASPICD.SYS /D:ASPICD0
8 rem **** IDE CDROM device drivers
9 DEVICE=C:\DOS\HIMEM.SYS
10 DEVICE=C:\SBCD\DRV\SBIDE.SYS /V /D:MSCD001 /P:1f0,14
13 DEVICE=C:\DOS\SETVER.EXE
16 DEVICE=C:\WINDOWS\SMARTDRV.EXE /DOUBLE_BUFFER
17 DEVICE=C:\WINDOWS\IFSHLP.SYS
Chapter 8. Rexx Utilities (RexxUtil)

8.26. SysFileSystemType (Windows only)

```
>>>-SysFileSystemType(drive)------------------------------------------------------>
```

Returns the name of the file system used for a drive. If the drive is not accessible, it returns a null string (""").

**Parameter:**

*drive*

The drive of interest, for example "C:".

**Example:**

```rxml
/* Code */
say "File System="SysFileSystemType("C:")
/* Output */
File System=NTFS
```

8.27. SysFileTree

```
>>>-SysFileTree(filespec,stem------------------------------------------------------>
```

Finds all files that match a file specification. SysFileTree returns the file descriptions (date, time, size, attributes, and file specification) space delimited in a Rexx stem variable collection. The default format for date and time is platform specific.

**Parameters:**

*filespec*

The search file specification.

*stem*

The name of a stem variable to be used for storing results. SysFileTree sets Rexx variable *stem.0* to the number of files and directories found and stores individual file descriptions into variables *stem.1* to *stem.n*. Note: *stem* can be specified as *stem or stem.* (with or without the trailing period)

*options*

A string with any combination of the following:
"F"
Search only for files.

"D"
Search only for directories.

"B"
Search for both files and directories. This is the default.

"S"
Search subdirectories recursively.

"T"
Return the time and date in the form YY/MM/DD/HH/MM. If the "L" option is also specified then this option will be ignored.

"L"
Return the time and date in the form YYYY-MM-DD HH:MM:SS.

"I"
Perform a case-insensitive search for file names/directories. This option is only used on system that support case-sensitive file names and is ignored on systems like Windows where the file system is case-insensitive by default.

"O"
Return only the fully-qualified file name.

tattrib
The target attribute mask for file specification matches. Only files that match the target mask are returned. The default mask is "*****". This returns all files regardless of the settings (clear or set) of the Archive, Directory, Hidden, Read-Only, and System attributes. The target mask attributes must appear in the order "ADHRS".

Target Mask Options

* The file attribute may be any state.

+ The file attribute must be set.

- The file attribute must be cleared.

Target Mask Examples
“***+*”
Find all files with the Read-Only attribute set.

“+***+*”
Find all files with the Read-Only and Archive attributes set.

“*+++**”
Find all hidden subdirectories.

“----+-”
Find all files with only the Read-Only attribute set.

**nattrib**

The new attribute mask for setting the attributes of each matching file. The default mask is “*****”. This means not to change the Archive, Directory, Hidden, Read-Only, and System attributes. The target mask attributes must appear in the order “ADHRS”.

New Attribute Mask Options

`
*  
Do not change the file attribute.

+  
Set the file attribute.

-  
Clear the file attribute.
`

New Attribute Mask Examples

“***+*”
Set the Read-Only attribute on all files.

“_++*+”
Set the Read-Only attribute and clear the Archive attribute of each file.

“++#+++”
Set all file attributes, except the directory attribute.

“-----”
Clear all attributes on all files.

**Note:** You cannot set the directory attribute on non-directory files. SysFileTree returns the file attribute settings after the new attribute mask has been applied.
Return codes:

0
  Successful.
2
  Not enough memory.

Examples:

/* Find all subdirectories on C: */
call SysFileTree "c:\*.\", "file", "SD"

/* Find all Read-Only files */
call SysFileTree "c:\*.\", "file", "S", "*****"

/* Clear Archive and Read-Only attributes of files that have them set */
call SysFileTree "c:\*.\", "file", "S", "*****", "-**-*"

/****<< Sample Code and Output Example.>>********/

/* Code */
call SysFileTree "c:\win*.\", "file", "B"
do i=1 to file.0
say file.i
end

/* Actual Output */
5:24:95 4:59p 0 -D--- C:\WINDOWS

8.28. SysFork (Unix only)

>>>SysFork()----------------------------------------------->

Returns

Returns the process id to the parent process.
Returns 0 to the spawned process.

Example:

This is a complete working example. It can be cut and pasted into a file and executed on a Unix system.

/* Example Unix SysFork() and SysWait() */

    pid = SysFork()
if pid == 0 then do
    say "I am the child."
    code = executeChild()
    say "Child : done with execution, will exit with" code
    exit code
end
else do
    say 'I am the parent, child pid is:' pid
    code = executeParent()
    say 'Parent: going to wait for child.'
    code = SysWait()
    say 'Parent: back from waiting. Child exit code:' code
end

say 'Operating system version:' SysVersion()

::routine executeChild

say 'Child : will sleep 1 second.'
j = SysSleep(1)
say 'Child : done sleeping 1. Will do some calculations.'

    total = 0
    do 786
        total += 3
    end

say 'Child : 3 * 786 is:' total

say 'Child : will sleep 2 seconds.'
j = SysSleep(2)
say 'Child : done sleeping 2. Will do some calculations.'

    total = 0
    do 1865
        total += 7
    end

say 'Child : 7 * 1865 is:' total

say 'Child : will sleep 2 seconds.'
j = SysSleep(2)
say 'Child : done sleeping 2.'
say 'Child : done executing, will return 0.'
return 0

::routine executeParent

say 'Parent: 3 * 786 is:' (3 * 786)
j = SysSleep(2)
say 'Parent: 7 * 1865 is:' (7 * 1865)
return 0
Chapter 8. ReXX Utilities (ReXXUtil)

8.29. SysFromUnicode (Windows only)

Maps a UNICODE character string to an ASCII character string. The new character string and additional information is returned in the outstem.

**Parameters:**

*string*

A string containing the UNICODE characters to be mapped.

*codepage*

Specifies the code page used to perform the conversion. This parameter can be the value of any code page that is installed or available in the system. The default is the current original equipment manufacturer (OEM) code-page identifier for the system.

You can also specify one of the following values:

- **ACP**
  ANSI code page.
- **OEMCP**
  OEM code page.
- **SYMBOL**
- **THREAD_ACP**
- **UTF7**
- **UTF8**
  Windows NT 4.0 and Windows 2000: translate using UTF-8. When this is set, *mappingflags* must be set.

*mappingflags*

Specifies the handling of unmapped characters. The function performs more quickly when none of these flags is set.

The following flags can be used:
Chapter 8. Rexx Utilities (RexxUtil)

COMPOSITECHECK

Converts composite characters to precomposed characters.

SEPCHARS

Generates separate characters during conversion. This is the default conversion behavior.

DISCARDNS

Discards nonspacing characters during conversion.

DEFAULTCHAR

Replaces non-convertible characters with the default character during conversion.

When compositecheck is specified, the function converts composite characters to precomposed characters. A composite character consists of a base character and a nonspacing character, each having different character values. A precomposed character has a single character value for a combination of a base and a nonspacing character. In the character è, the "e" is the base character, and the "grave" accent mark is the nonspacing character.

When compositecheck is specified, it can use the last three flags in this list (discardns, sepchars, and defaultchar) to customize the conversion to precomposed characters. These flags determine the function's behavior when there is no precomposed mapping for a combination of a base and a nonspase character in a Unicode character string. These last three flags can be used only if the compositecheck flag is set. The function's default behavior is to generate separate characters (sepchars) for unmapped composite characters.

defaultchar

Character to be used if a Unicode character cannot be represented in the specified code page. If this parameter is NULL, a system default value is used. The function is faster when defaultchar is not used.

outstem

The name of the stem variable that will contain the converted result. If the conversion was successful the stem will be composed of the following value(s):

outstem.!USEDDEFAULTchar

This variable will be set to "1" if the defaultchar was used during the conversion and "0" if it was not.

outstem.!TEXT

This variable will contain the converted string.

Return codes:

0

No errors.
Other

An error occurred. A Windows System Error code is returned. This may be one of the following, but could be others.

87

Incorrect code page or codepage value.

1004

Invalid mapping flags.

8.30. SysGetErrortext

>>>-SysGetErrortext(errnumber)--------------------------------><

Obtains a string describing the system error identified by the error number.

Returns a string with the description of the error, or an empty string if no description is available.

Windows Example:

err=SysMkDir("c:\temp")
if err \= 0 then
say "Error" err":"SysGetErrortext(err)

Unix Example:

err=SysMkDir("/home/NotKnown/temp")
if err \= 0 then
say "Error" err":"SysGetErrortext(err)

8.31. SysGetFileDateTime

>>>-SysGetFileDateTime(filename+-+------------+-)----------------><

Returns the selected data and time attribute of the file filename provided that this is supported by the operating and file system. FAT, for example, does not support Create/Access. The selector for the time to be returned can be abbreviated to the first character.

The filename can also be a directory name.

The file that you want to query must not be opened by another process or must at least allow shared writes to query the time stamp.

Parameters:

filename

The name of the file to be queried.
Chapter 8. Rexx Utilities (RexxUtil)

timesel

The file time to be queried, namely CREATE, ACCESS, WRITE.

Return codes:
The date and time in the format YYYY-MM-DD HH:MM:SS, or -1 to indicate that the file date and time
query failed.

Example:

Say "File creation time:" SysGetFileDateTime("MyFile.Log", "C")
Say "File last access time:" SysGetFileDateTime("MyFile.Log", "A")
Say "File last update time:" SysGetFileDateTime("MyFile.Log", "W")

Say "Directory creation time:" SysGetFileDateTime("C:\MyDir", "C")
    /* in Windows NT */

8.32. SysGetKey

    >>-SysGetKey(--+-+---+-)----------------------------------------><
    +-opt-+

Reads and returns the next key from the keyboard buffer. If the keyboard buffer is empty, SysGetKey
waits until a key is pressed. Unlike the CHARIN built-in function, SysGetKey does not wait until the
Enter key is pressed.

Parameter:

opt

An option controlling screen echoing. Allowed values are:

"ECHO"

    Echo the pressed key to the screen. This is the default.

"NOECHO"

    Do not echo the pressed key.

8.33. SysGetMessage (Unix only)

    >>-SysGetMessage(num--+-+---+-)----------------------------------------><
    +-+-+----------+-+---+-+-+----------+-
    | | | +---+---+-+ | |
    | | | V | | | |
    | +-----+---+-+ | |
    | V | | | |
    +-----+---+-+ |

    ooRexx Reference Version 4.0.0
Chapter 8. Rexx Utilities (RexxUtil)

Retrieves a message from a catalog file and replaces the placeholder %s with the text you specify. SysGetMessage can replace up to 9 placeholders.

This utility is implemented for Unix only.

To create catalog files, consult your system documentation.

Parameters:

num

The message number.

filename

The name of the catalog file containing the message. The default message catalog is rexx.cat. SysGetMessage searches along the NLSPATH or uses the absolute path name.

str

The test for a placeholder (%) in the message. The message can contain up to 9 placeholders. You must specify as many strings as there are placeholders in the message.

Example:

/* sample code segment using SysGetMessage */
msg = SysGetMessage(485, "rexx.cat", foo)
say msg
/** Output ***/
Class "foo" not found.

8.34. SysGetMessageX (Unix only)

Retrieves a message from a specific set of Unix catalog file and replaces the placeholder %s with the text you specify. SysGetMessageX can replace up to 9 placeholders.

This utility is implemented for Unix only. Do not use it for platform-independent programs.

To create catalog files, consult your system documentation.

Parameters:

set

The message set.
Chapter 8. Rexx Utilities (RexxUtil)

num
The message number.

filename
The name of the catalog file containing the message. The default message catalog is rexx.cat. SysGetMessageX searches along the NLSPATH or uses the absolute path name.

str
The test for a placeholder (%) in the message. The message can contain up to 9 placeholders. You must specify as many strings as there are placeholders in the message.

Example:
```rexx
/* sample code segment using SysGetMessage */
msg = SysGetMessageX(1, 485, "rexx.cat", foo)
say msg
/*** Output ***/
Class "foo" not found.
```

8.35. SysIni (Windows only)

>>-SysIni(-----------+-,app,key,val,stem-)---------------------><
+-inifile--
Allows limited access to INI file variables. Variables are stored in the INI file under Application Names and their associated key names or keywords. You can use SysIni to share variables between applications or as a way of implementing GLOBALV in the Windows operating system. Be careful when changing application profile information.

Note: SysIni works on all types of data stored in an INI file (text, numeric, or binary).

When SysIni successfully sets or deletes key values, it returns "". For a successful query, it returns the value of the specified application keyword.

SysIni may return the string ERROR: when an error occurs. Possible error conditions include:

- An attempt was made to query or delete an application/key pair that does not exist.
- An error opening the profile file occurred. You may have specified the current user or system INI file with a relative file specification. Make sure to use the full file specification (specify drive, path, and file name).

Parameters:
inifile

The name of the INI file with which you would like to work. The default is WIN.INI.

Note: If this argument does not contain a fully qualified file name, the Windows operating system searches for the file in the Windows directory. Therefore to work with a file outside of the Windows directory, specify the full path name of the file.

app

The application name or some other meaningful value with which you want to store keywords (some sort of data).

key

The name of a keyword to hold data.

val

The value to associate with the keyword of the specified application. This can be "DELETE:" or "ALL:"

stem

The name of a Rexx stem variable collection in which to store the resultant information. SysIni sets Rexx variable stem.0 to the number of elements returned and stores these elements in stem.1 to stem.n.

Sysini has six modes. The modes and the syntax variations are as follows:

>>-SysIni(-+---------+-,app,key,val)--------------------------<
    +inifile+-

Sets a single key value.

>>-SysIni(-+---------+-,app,key)--------------------------<
    +inifile+-

Queries a single key value.

>>-SysIni(-+---------+-,app,key-,"DELETE:"-)------------------><
    +inifile+-

Deletes a single key.

>>-SysIni(-+---------+-,app+-+------------+-)------------------><
    +inifile+- +-,"DELETE:"+-

Deletes an application and all associated keys.

>>-SysIni(-+---------+-,app-,"ALL:"-,"stem")------------------><
    +inifile+-

Queries names of all keys associated with a certain application.
Chapter 8. Rexx Utilities (RexxUtil)

Queries the names of all applications.

Examples:

/* Sample code segments */

/*** Save the user entered name under the key "NAME" of *****
**** the application "MYAPP". *****
pull name.
call SysIni, "MYAPP", "NAME", name /* Save the value */
say SysIni(, "MYAPP", "NAME") /* Query the value */
call SysIni, "MYAPP" /* Delete all MYAPP info */
exit

/**** Type all WIN.INI file information to the screen *****
call SysIni "WIN.INI", "All:", "Apps."
if Result != "ERROR:" then
do i = 1 to Apps.0
call SysIni "WIN.INI", Apps.i, "All:", "Keys"
if Result != "ERROR:" then
do j=1 to Keys.0
val = SysIni("WIN.INI", Apps.i, Keys.j)
say left(Apps.i, 20) left(Keys.j, 20),
"Len=x"Left(d2x(length(val)),4) left(val, 20)
end
end
exit

8.36. SysIsFile

Checks for the existence of a file. This function does not support wildcard specifications.
On Linux/Unix block devices are also considered to be regular files by this function.

Parameters:

filename

The name of the file to check for the existence of.

Returns:

0

The file does not exist.
Chapter 8. Rexx Utilities (RexxUtil)

The file exists.

Example:

if SysIsFile(InputFile) then say "File Exists!"
else say "File does not exist."

8.37. SysIsFileCompressed (Windows only)

Checks if a file is compressed. This function does not support wildcard specifications.

Parameters:

filename

The name of the file to check.

Returns:

0

The file is not compressed or does not exist.

1

The file is compressed.

Example:

if SysIsFileCompressed(InputFile) then say "File is compressed!"
else say "File is not compressed or does not exist."

8.38. SysIsFileDirectory

Checks for the existence of a subdirectory. This function does not support wildcard specifications.

Parameters:

dirname

The name of the subdirectory to check for the existence of.

Returns:
0
   The subdirectory does not exist.

1
   The subdirectory exists.

Example:

if SysIsFileDirectory(InputFile) then say "Subdirectory Exists!"
else say "Subdirectory does not exist."

---

8.39. SysIsFileEncrypted (Windows only)

>>-SysIsFileEncrypted(filename)---------------------------------><

Checks if a file is encrypted. This function does not support wildcard specifications.

Parameters:

filename
   The name of the file to check.

Returns:

0
   The file is not encrypted or does not exist.

1
   The file is encrypted.

Example:

if SysIsFileEncrypted(InputFile) then say "File is encrypted!"
else say "File is not encrypted or does not exist."

---

8.40. SysIsFileLink

>>-SysIsFileLink(linkname)--------------------------------------><

Checks for the existence of a link. This function does not support wildcard specifications.

Parameters:
Chapter 8. Rexx Utilities (RexxUtil)

8.41. SysIsFileNotContentIndexed (Windows only)

>>>-SysIsFileNotContentIndexed(filename)------------------------><

Checks if a file is flagged to be indexed by the Index Service. This function does not support wildcard specifications.

Parameters:

filename

The name of the file to check.

Returns:

0

The file is not flagged to be Indexed or does not exist.

1

The file is flagged to be Indexed.

Example:

if SysIsFileNotContentIndexed(InputFile) then say "File is flagged to be Indexed!"
else say "File is not flagged to be Indexed."

8.42. SysIsFileOffline (Windows only)

>>>-SysIsFileOffline(filename)----------------------------------><

Checks if a file is flagged as Offline. This function does not support wildcard specifications.

Arguments:

filename

The name of the file to check.

Returns:

0

The file is not flagged as Offline or does not exist.

1

The file is flagged as Offline.

Example:

if SysIsFileOffline(InputFile) then say "File is flagged as Offline!"
else say "File is not flagged as Offline."
Chapter 8. Rexx Utilities (RexxUtil)

Parameters:

filename
    The name of the file to check.

Returns:

0
    The file is not flagged as Offline or does not exist.

1
    The file is flagged as Offline.

Example:

if SysIsFileOffline(InputFile) then say "File is flagged as Offline!"
else say "File is not flagged as Offline."

8.43. SysIsFileSparse (Windows only)

>>>-SysIsFileSparse(filename)---------------------------------->

Checks if a file is flagged as Sparse. This function does not support wildcard specifications.

Parameters:

filename
    The name of the file, subdirectory or link to check.

Returns:

0
    The file is not flagged as Sparse or does not exist.

1
    The file is flagged as Sparse.

Example:

if SysIsFileSparse(InputFile) then say "File is Sparse!"
else say "File is not Sparse."

8.44. SysIsFileTemporary (Windows only)

>>>-SysIsFileTemporary(filename)-------------------------------<
Checks if a file is flagged as Temporary. This function does not support wildcard specifications.

**Parameters:**

_filename_

The name of the file, subdirectory or link to check.

**Returns:**

0

The file is not flagged as Temporary or does not exist.

1

The file is flagged as Temporary.

**Example:**

```rexx
if SysIsFileTemporary(InputFile) then say "File is Temporary!"
else say "File is not Temporary."
```

### 8.45. **SysLinVer (Linux Only)**

```
>>-SysLinVer()-------------------------------------------------><
```

Returns a string identifying the Linux system version. The first word of the returned string is Linux and the second word in the string identifies the kernel version. A possible output for a Linux system might be:

```rexx
Say SysLinVer() -> "Linux 2006.2.6.18-1.2798.fc6"
```

### 8.46. **SysLoadFuncs**

```
>>-SysLoadFuncs------------------------------------------------><
```

From ooRexx 4.0.0 and on this function does nothing.

### 8.47. **SysLoadRexxMacroSpace**

```
>>-SysLoadRexxMacroSpace(file)---------------------------------><
```

Loads functions from a saved macrospace file. SysLoadRexxMacroSpace returns the RexxLoadMacroSpace return code.

**Parameter:**
The file used to load functions into the Rexx macrospace. SysSaveRexxMacroSpace must have created the file.

**8.48. SysMkDir**

```
>>-SysMkDir(dirspec)-------------------------------------------><
```

Creates a specified directory.

**Parameter:**

`dirspec`

The directory to be created.

**Return codes:**

0

Directory creation was successful.

Other

An error occurred. On Windows, a Windows System Error code is returned. This may be one of the following, but could be others.

2

File not found.

3

Path not found.

5

Access denied.

26

Not a DOS disk.

87

Invalid parameter.

108

Drive locked.

183

Directory already exists.
206

File name exceeds range.

Example:

/* Code */
call SysMkDir "rexx"

8.49. **SysOpenEventSem**

>>>-SysOpenEventSem(name)-------------------------------------->><

Opens an event semaphore. SysOpenEventSem returns a handle to the semaphore, or zero if an error occurred.

**Parameter:**

*name*

The name of the event semaphore created by SysCreateEventSem.

8.50. **SysOpenMutexSem**

>>>-SysOpenMutexSem(name)-------------------------------------->><

Opens a mutex semaphore. SysOpenMutexSem returns a handle to the semaphore, or zero if an error occurred.

**Parameter:**

*name*

The name of the mutex semaphore created by SysCreateMutexSem.

8.51. **SysPostEventSem**

>>>-SysPostEventSem(handle)------------------------------------->><

Posts an event semaphore.

**Parameter:**

*handle*

A handle returned from a previous SysCreateEventSem call.

**Return codes:**
8.52. SysPulseEventSem (Windows only)

Posts and immediately resets an event semaphore. It sets the state of the event to signaled (available), releases any waiting threads, and resets it to nonsignaled (unavailable) automatically. If the event is manual, all waiting threads are released, the event is set to nonsignaled, and PulseEvent returns. If the event is automatic, a single thread is released, the event is set to nonsignaled, and PulseEvent returns. If no threads are waiting, or no threads can be released immediately, PulseEvent sets the state of the event to nonsignaled and returns.

SysPulseEventSem returns 0 on success and a Windows System Error code is returned on error.

Parameter:

*handle*

The handle of an event semaphore previously created by SysCreateEventSem.

8.53. SysQueryProcess

Windows

```plaintext
>>>-SysQueryProcess(" +++++PID------ ")--------------------------------><
+PPRID++
+PPRIO++
+TPRIO++
+PTIME++
+TTIME++
```

Unix

```plaintext
>>>-SysQueryProcess(" +++++PID------ ")--------------------------------><
+PPPID------
+PPRIO------
+PPRIO------
+PTIME------
+PMEM------
```
Chapter 8. Rexx Utilities (RexxUtil)

Retrieves information about the current process or Windows thread.

**Parameter:**

`info`

The kind of information requested:

- **PID**
  Returns the process ID of the current process.

- **PPID**
  Returns the parent process ID of the current process.

- **TID**
  Returns the thread ID of the current thread.

- **PPRIO**
  Returns the priority class of the current process.

- **TPRIO**
  Returns the relative priority of the current thread.

- **PTIME**
  Returns time information on the current process.

- **TTIME**
  Returns time information on the current thread.

- **PMEM**
  Returns the maximum memory (RSS) used by the current process.

- **PRCVDSIG**
  Returns the number of signals that have been received by the process.

**Return codes:**

- For PID, PPID or TID: an ID
- For Windows PPRIO: "IDLE", "NORMAL", "HIGH", "REALTIME", or "UNKNOWN"
- For Unix PPRIO: a number from -20 to +20.
- For TPRIO: "IDLE", "LOWEST", "BELOW_NORMAL", "NORMAL", "ABOVE_NORMAL", "HIGHEST", "TIME_CRITICAL", or "UNKNOWN"
Chapter 8. Rexx Utilities (RexxUtil)

- For Windows PTIME or TTIME: the creation date and time, the amount of time that the process executed in kernel mode, and the amount of time that the process executed in user mode
- For Unix PTIME: the summary and the duration that the process executed in kernel mode, and the duration that the process executed in user mode

8.54. SysQueryRexxMacro

```
>>> SysQueryRexxMacro(name)
```

Queries the existence of a macrospace function. SysQueryRexxMacro returns the placement order of the macrospace function or a null string (""") if the function does not exist in the macrospace.

**Parameter:**

`name`

The name of a function in the Rexx macrospace.

8.55. SysReleaseMutexSem

```
>>> SysReleaseMutexSem(handle)
```

Releases a mutex semaphore.

**Parameter:**

`handle`

A handle returned from a previous SysCreateMutexSem call.

**Return codes:**

0

No errors.

Other

An error occurred. On Windows, a Windows System Error code is returned. This may be one of the following, but could be others.

6

Invalid handle.

105

Owner died.
288
Not owner.

8.56. **SysReorderRexxMacro**

```plaintext
>>-SysReorderRexxMacro(name,order)-----------------------------><
```

Reorders a routine loaded in the Rexx macro space. `SysReorderRexxMacro` returns the `RexxReorderMacro` return code.

**Parameters:**

- **name**
  
  The name of a function in the macro space.

- **order**
  
  The new macro search order. The order can be "B" (Before) or "A" (After).

8.57. **SysRequestMutexSem**

```plaintext
>>-SysRequestMutexSem(handle,timeout)--------------------------><
```

Requests a mutex semaphore. `SysRequestMutexSem` returns the `WaitForSingleObject` return code.

**Parameters:**

- **handle**
  
  A handle returned from a previous `SysCreateMutexSem` call.

- **timeout**
  
  The time, in milliseconds, to wait on the semaphore. The default `timeout` is an infinite wait.

**Return codes:**

- **0**
  
  No errors.

- **Other**
  
  An error occurred. On Windows, a [Windows System Error code](#) is returned. This may be one of the following, but could be others.

- **6**
  
  Invalid handle.
8.58. **SysResetEventSem**

```plaintext
>>>-SysResetEventSem(handle)------------------------------------><
```

Resets an event semaphore.

**Parameter:**

`handle`

A handle returned from a previous SysCreateEventSem call.

**Return codes:**

0

No errors.

Other

An error occurred. On Windows, a Windows System Error code is returned. This may be one of the following, but could be others.

6

Invalid handle.

8.59. **SysRmDir**

```plaintext
>>>-SysRmDir(dirspec)------------------------------------------><
```

Deletes a specified file directory without your confirmation.

**Parameter:**

`dirspec`

The directory that should be deleted.

**Return codes:**

0

Directory removal was successful.
Other

An error occurred. On Windows, a Windows System Error code is returned. This may be one of the following, but could be others.

2
File not found.

3
Path not found.

5
Access denied or busy.

16
Current directory.

26
Not a DOS disk.

32
Sharing violation.

108
Drive locked.

123
Invalid name.

145
Directory not empty.

146
Is Subst Path.

147
Is Join Path.

206
File name exceeds range.

Example:

/* Code */
call SysRmDir "c:\rexx"
8.60. **SysSaveRexxMacroSpace**

```
>>>-SysSaveRexxMacroSpace(file)---------------------------------><
```

Saves the Rexx macrospace. SysSaveRexxMacroSpace returns the RexxSaveMacroSpace return code.

**Parameter:**

*file*

The file used to save the functions in the Rexx macrospace.

8.61. **SysSearchPath**

```
>>>-SysSearchPath(path,filename+-----------+-)-----------------><
   +-,--option-+
```

Searches the specified file path for the specified file. If the file is found, the search returns the full file specification of the first file found within the path, and then stops searching. If the file is not found, the search returns a null string.

**Parameters:**

*path*

An environment variable name. The environment variable must contain a list of file directories. Examples are "PATH" or "DPATH".

*filename*

The file for which the path is to be searched.

*option*

Specifies where the search starts.

"C"

Starts the search at the current directory and then along the specified path. This is the default.

"N"

Starts the search at the path, not at the current directory.

**Example:**

```r
/* Code */
fspec = SysSearchPath("PATH", "CMD.EXE")
say "CMD.EXE is located at" fspec

/* Output */
CMD.EXE is located at C:\WIN\CMD.EXE
```
8.62. **SysSetFileDateTime**

```
>>-SysSetFileDateTime(filename----+---------------------------------+-->)
     ++-+-+-----------------------------------+-+
     +--newdate-+ +-,--newtime-+
```

Modifies the "Last Modified" date and time of file *filename*. If no new date or time is specified the file date or time is set to the current time (TOUCH). If only the date is omitted, the "Last Modified" date remains unchanged. If only the time is omitted, the "Last Modified" time remains unchanged.

The *filename* can also be a directory name.

The file that you want to change must not be opened by another process or must at least allow shared writes to update the time stamp.

**Parameters:**

- **filename**
  The name of the file to be updated.

- **newdate**
  The new date for the file, to be specified in the format YYYY-MM-DD, where YYYY > 1800.

- **newtime**
  The new time for the file, to be specified in the format HH:MM:SS (24-hour format).

**Return codes:**

- **0**
  The file date and time were updated correctly.

- **-1**
  The update of the file date or time failed.

**Example:**

```rexx
Call SysSetFileDateTime "MyFile.Log" /* touch file */
Call SysSetFileDateTime "MyFile.Log", "1998-12-17"
Call SysSetFileDateTime "MyFile.Log", , "16:37:21"
Call SysSetFileDateTime "MyFile.Log", "1998-12-17", "16:37:21"

Call SysSetFileDateTime "C:\MyDir" /* touch dir on Windows NT */
```

8.63. **SysSetPriority**

```
>>-SysSetPriority(class,delta)------------------------------->)
```

Changes the priority of the current process. A return code of 0 indicates no error.

**Parameters:**

```rexx
```
Chapter 8. Rexx Utilities (RexxUtil)

**class**

The new process priority class. The allowed classes are:

0 or "IDLE"
   Idle time priority
1 or "NORMAL"
   Regular priority
2 or "HIGH"
   High or time-critical priority
3 or "REALTIME"
   Real-time priority

**delta**

The change applied to the process priority level. *delta* must be in the range -15 to +15. It can also be a symbolic name:

- "IDLE" for -15
- "LOWEST" for -2
- "BELOW_NORMAL" for -1
- "NORMAL" for 0
- "ABOVE_NORMAL" for 1
- "HIGHEST" for 2
- "TIME_CRITICAL" for 15

0

No errors.

**Other**

An error occurred. A Windows System Error code is returned. This may be one of the following, but could be others.

307

Invalid priority class.

**8.64. SysShutdownSystem (Windows only)**

```rxml
>>>-SysShutdownSystem(------------------------------------------->
>--+------------------------------------------------------+-)--><
```
Chapter 8. Rexx Utilities (RexxUtil)

Shuts down the system.

**Parameters:**

*computer*

Name of the remote machine. "" = local.

*message*

message for dialog.

*timeout*

Time to display message.

*appclose*

No dialog "save unsaved data".

*reboot*

1 to reboot the system.

**Returns:**

Returns 0 for success or a Windows System Error code for failure.

### 8.65. SysSleep

```ruby
>>>-SysSleep(secs)---------------------------------------------->
```

Pauses a Rexx program for a specified time interval.

**Parameter:**

*secs*

The number of seconds for which the program is to be paused. You can specify up to seven decimal places in the number.

**Example:**

Say "Now paused for 2 seconds . . ."
Call SysSleep 2
Say "Now paused for 0.1234567 seconds . . ."
Call SysSleep 0.1234567
Call SysSleep 0.12345678 -- Error 40: Incorrect call to routine
8.66. SysStemCopy

Copies items from the source stem to the target stem. Items in the source stem are copied starting at the
from index (default is 1) into the target stem beginning at the to index (default is 1). The number of items
to be copied to the target stem can be specified with the count. The default is to copy all items in the
source stem.

You can also specify that the items are to be inserted into the target stem at the position and the existing
items are shifted to the end.

This function operates only on stem arrays that specify the number of items in stem.0 and all items must
be numbered from 1 to n without omitting an index.

Parameters:

fromstem
    The name of the source stem.

tostem
    The name of the target stem.

from
    The first index in the source stem to be copied.

to
    The position at which the items are to be inserted in the target stem.

count
    The number of items to be copied or inserted.

insert
    Either of the following values:

    I
        Insert items.

    O
        Overwrite items.

Return codes:
The stem was copied successfully.

Copying the stem failed.

Example:

Source.0 = 3
Source.1 = "Hello"
Source.2 = "from"
Source.3 = "Rexx"
Call SysStemCopy "Source.", "Target."

Call SysStemCopy "Source.", "Target.", 1, 5, 2, "I"

8.67. SysStemDelete

Deletes the specified item at the index startitem in the stem. If more than one item is to be deleted the itemcount must be specified. After deleting the requested items the stem is compacted, which means that items following the deleted items are moved to the vacant positions.

This function operates only on stem arrays that specify the number of items in stem.0 and all items must be numbered from 1 to n without omitting an index.

Parameters:

stem

The name of the stem from which the item is to be deleted.

startitem

The index of the item to be deleted.

itemcount

The number of items to be deleted if more than one.

Return codes:

0

Deleting was successful.

-1

Deleting failed.

Example:
Call SysStemDelete "MyStem.", 5
Call SysStemDelete "MyStem.", 5, 4

8.68. SysStemInsert

>>-SysStemInsert(stem,position,value)--------------------------><

Inserts a new item at position in the stem. All items in the stem following this position are shifted down by one position.

This function operates only on stem arrays that specify the number of items in stem.0 and all items must be numbered from 1 to n without omitting an index.

Parameters:

stem
The name of the stem in which an item is to be inserted.

position
The index at which the new item is to be inserted.

value
The value of the new item.

Return codes:

0
Inserting was successful.

-1
Inserting failed.

Example:

Call SysStemInsert "MyStem.", 5, "New value for item 5"

8.69. SysStemSort

++A++ ++C++ ++I-----+

>>-SysStemSort--(--stem--,--"---D---"--,--"---I++"--,--start--->

++I------+

>>--end--,--firstcol--++,--lastcol--)-----------------------------><

Sorts all or the specified items in the stem. The items can be sorted in ascending or descending order and the case of the strings being compared can be respected or ignored. Sorting can be further narrowed by
specifying the first and last item to be sorted or the columns used as sort keys. Because the sort uses a quick-sort algorithm, the order of sorted items according to the sort key is undetermined.

This function operates only on stems that specify the number of items in stem.0 and all items must be numbered from 1 to n without omitting an index. A value of 0 in stem.0 is also valid but no sort will be performed.

**Parameters:**

*stem*

The name of the stem to be sorted.

*order*

Either "A" for ascending or "D" for descending. The default is "A".

*type*

The type of comparison: either "C" for case or "I" for ignore. The default is "C".

*start*

The index at which the sort is to start. The default is 1.

*end*

The index at which the sort is to end. The default is the last item.

*firstcol*

The first column to be used as sort key. The default is 1.

*lastcol*

The last column to be used as sort key. The default is the last column.

**Return codes:**

0

The sort was successful.

-1

The sort failed.

**Example:**

/* sort all elements descending, use cols 5 to 10 as key */
Call SysStemSort "MyStem.", "D", , , 5, 10

/* sort all elements ascending, ignore the case */
Call SysStemSort "MyStem.", "A", "I"

/* sort elements 10 to 20 ascending, use cols 1 to 10 as key */
Call SysStemSort "MyStem.", , ,10, 20, 1, 10
Chapter 8. Rexx Utilities (RexxUtil)

8.70. SysSwitchSession (Windows only)

```plaintext
>>-SysSwitchSession(name)--------------------------------------><
```

Brings the named window to the foreground. Modern versions of Windows do not always allow a window to be brought to the foreground programmatically. Instead, the icon for the window on the task bar is set to flashing.

**Parameter:**

*name*

The name of the window you want to be the foreground window. The name of the window must exactly match the title of the window, but is not case sensitive. The title of a window is the text displayed in its title bar.

O is returned on success and a [Windows System Error code](#) on failure.

8.71. SysSystemDirectory (Windows only)

```plaintext
>>-SysSystemDirectory()----------------------------------------><
```

Returns the Windows system directory.

8.72. SysTempFileName

```plaintext
>>-SysTempFileName(template-+---------+-)----------------------><
+-,filter-+
```

Returns a unique name for a file or directory that does not currently exist. If an error occurs or SysTempFileName cannot create a unique name from the template, it returns a null string ("""). SysTempFileName is useful when a program requires a temporary file.

**Parameters:**

*template*

The location and base form of the temporary file or directory name. The *template* is a valid file or directory specification with up to five filter characters.

SysTempFileName generates the filter character replacements with a random number algorithm. If the resulting file or directory already exists, SysTempFileName increments the replacement value until all possibilities have been exhausted.

There are slight differences in how the template works on Windows and Unix/Linux.

On Windows: The file name part of the template can be any length. However, the template must contain at least 1 filter character or the empty string is returned. The unique name is created solely by substituting random numbers for the filter character(s). If there is a directory name part of the template in addition to the file name part, and the directory name part contains a non-existent
directory, the function will succeed. However, the temporary file will not be writable unless the user
first creates the non-existent directory, or directories. When the function succeeds, the result is
always the same length as the template.

On Unix/Linux: Only the first five characters of the file name part of the template are used. Any
characters after the first five in the file name part are ignored. The unique name is generated by the
operating system adding a random string of characters to the end of the template. The template
does not have to include any filter characters. If the template does include filter characters, then
ooRexx replaces those filter characters with random numbers. Because the operating system adds a
random string to the end of the template, the result will always be longer than the template. In
general, if the template does not contain a directory part, or if the directory part is not writable by
the user, a writable directory part is added by the operating system (most likely /tmp.) This last
behavior may vary depending on the exact version of the Unix/Linux operating system.

filter

The filter character used in template. SysTempFileName replaces each filter character in template
with a numeric value. The resulting string represents a file or directory that does not exist. The
default filter character is ?.

Examples:

/* Windows Code */
say SysTempFileName("C:\TEMP\MYEXEC.???")
say SysTempFileName("C:\TEMP\MYEXEC.tmp")    -- produces the empty string.
say SysTempFileName("C:\TEMP\??MYEXEC.???")
say SysTempFileName("C:\MYEXEC@.@@@", "@")

/* Output */
C:\TEMP\MYEXEC .251
C:\TEMP\MYEXEC .392
C:\MYEXEC .019

/* Unix/Linux Code. mydir is an existing directory. */

say SysTempFileName("/mydir/MYEXEC.???")    -- filter characters are ignored
say SysTempFileName("/mydir/MYEXEC.tmp")    -- produces a unique name
say SysTempFileName("/mydir/??MYEXEC.???")
say SysTempFileName("/bogusdir/??MYEXEC.???")
say SysTempFileName("MYEXEC@.@@@", "@")

/* Output */
/mydir/MYEXECqY2Hd
/mydir/MYEXEC74dwdz
/mydir/77MYElnI0IU
/tmp/77MYEjowoeg
/tmp/MYEXECNj3JB
8.73. **SysTextScreenRead (Windows only)**

```plaintext
>>-SysTextScreenRead(-row, column--+-++-+-)--------------><
+-,len+-
```

Reads characters from a specified screen location. These include any carriage return and linefeed characters if the number of character reads spans multiple lines.

**Parameters:**

- `row`
  - The row from which to start reading.
- `col`
  - The column from which to start reading.
- `len`
  - The number of characters to read. The default is to read to the end of the screen.

Note that, on error, a [Windows System Error code](#) is returned.

**Limitations:** This function reads in only screen characters and does not consider the color attributes of each character read. When restoring a character string to the screen with `SAY` or the `CHAROUT` built-in function, the previous color settings are lost.

**Examples:**

```plaintext
/* Reading the entire screen */
screen = SysTextScreenRead(0, 0)

/* Reading one line */
line = SysTextScreenRead(2, 0, 80)
```

8.74. **SysTextScreenSize (Windows only)**

```plaintext
>>-SysTextScreenSize()----------------------------------------->
```

Returns the size of the screen in the format: `row col`.

**Example:**

```plaintext
/* Code */
call RxFuncAdd "SysTextScreenSize", "RexxUtil", "SysTextScreenSize"
parse value SysTextScreenSize() with row col
say "Rows="row", Columns="col
```
8.75. SysToUnicode (Windows only)

```rexx
>>-SysToUnicode--(--string, codepage, translateflags, outstem--)--><
```

Maps a character string to a UNICODE string.

**Parameters:**

*string*

A string containing the UNICODE characters to be mapped.

*codepage*

Specifies the code page used to perform the conversion. This parameter can be the value of any code page that is installed or available in the system. The default is the current original equipment manufacturer (OEM) code-page identifier for the system.

You can also specify one of the following values:

- ACP
  - ANSI code page.
- OEMCP
  - OEM code page.
- SYMBOL
- THREAD_ACP
- UTF7
- UTF8
  - Windows NT 4.0 and Windows 2000: translate using UTF-8. When this is set, `translateflags` must be set.

*translateflags*

Indicates whether to translate to precomposed or composite-wide characters (if a composite form exists), whether to use glyph characters in place of control characters, and how to deal with invalid characters.

You can specify a combination of the following flags:
PRECOMPOSED

Always use precomposed characters, that is, characters in which a base character and a nonspacing character have a single character value. This is the default translation option. Cannot be used with COMPOSITE.

COMPOSITE

Always use composite characters, that is, characters in which a base character and a nonspacing character have different character values. Cannot be used with PRECOMPOSED.

ERR_INVALID_CHARS

If the function encounters an invalid input character, it fails and returns "1113".

USEGLYPHCCHARS

Use glyph characters instead of control characters.

A composite character consists of a base character and a nonspacing character, each having different character values. A precomposed character has a single character value for a base-nonspacing character combination. In the character è, the "e" is the base character and the "grave" accent mark is the nonspacing character. The function’s default behavior is to translate to the precomposed form. If a precomposed form does not exist, the function attempts to translate to a composite form.

The flags PRECOMPOSED and COMPOSITE are mutually exclusive. The USEGLYPHCCHARS flag and the ERR_INVALID_CHARS can be set regardless of the state of the other flags.

outstem

The name of the stem variable that will contain the converted result. If the conversion was successful the stem will be composed of the following value(s):

outstem.!TEXT

This variable will contain the converted string.

Return codes:

0

No errors.

Other

An error occurred. A Windows System Error code is returned. This may be one of the following, but could be others.

87

Incorrect code page or codepage value.

1004

Invalid translate flags.
No mapping for the Unicode character exists in the target code page.

8.76. SysUtilVersion

`>>>-SysUtilVersion()--------------------------------------------><`

Returns a version number that identifies the current level of the Rexx Utilities package. It can be used to verify the availability of certain functions.

Return code: The REXXUTIL version number in the format n.mm.

**Examples:**

Because this function was not part of the original packaging, a sample logic to check for a certain level of RexxUTIL can look as follows:

```rexx
If RxFuncQuery("SysUtilVersion") = 1 |,
    SysUtilVersion() < "2.00" Then
        Say "Your RexxUTIL.DLL is not at the current level"
```

If a specific function should be used that was added at a later REXXUTIL level a similar check can be performed by querying this function as follows:

```rexx
If RxFuncQuery("SysSetFileDateTime") = 1 Then
    Say "Your REXXUTIL.DLL is not at the current level"
```

8.77. SysVersion

`>>>-SysVersion()------------------------------------------------><`

Returns a string to identify the operating system and version. The first word of the returned string contains the identifier for the operating system and the rest of the string contains a operating specific version string. Something like: WindowsNT x or Linux x.

Some possible output for operating systems supported by ooRexx might be:

```rexx
Say SysVersion() -> "Linux #1 SMP Mon Oct 16 14:54:20 EDT 2006.2.6.18-1.2798.fc6"
Say SysVersion() -> "WindowsNT 5.00"
```

**Note:** This function can be used to replace the operating-system-specific functions SysWinVer(), and SysLinVer().
8.78. SysVolumeLabel (Windows only)

```plaintext
>>-SysVolumeLabel(--+-------------+--)-------------------------------><
   +-driveLetter-+

Returns the volume label for the specified drive.

Parameter:

driveLetter
   A drive letter in the form 'X:'. If the drive letter is omitted than the current drive is used.

Return codes:

0
   Encryption was successful.

2
   File not found.

4
   Cannot open file.

5
   Access denied.

82
   Cannot encrypt.
```

8.79. SysWait (Unix only)

```plaintext
>>-SysWait()--------------------------------------------------><

Waits for all child processes to end.

Returns:

The exit code from the child process.

Example:

SysFork() has an example that uses wait().
```

8.80. SysWaitEventSem

```plaintext
>>-SysWaitEventSem(handle+-+----------+-)-----------------------><
   +-timeout-+

+-,timeout+-
```
Waits on an event semaphore. SysWaitEventSem returns the WaitForSingleObject return code.

**Parameters:**

*handle*

A handle returned from a previous SysCreateEventSem call.

*timeout*

The time, in milliseconds, to wait on the semaphore. The default *timeout* is an infinite wait.

**Return codes:**

0

No errors.

Other

An error occurred. On Windows, a [Windows System Error code](#) is returned. This may be one of the following, but could be others.

6

Invalid handle.

258

Timeout.

### 8.81. SysWaitNamedPipe (Windows only)

```plaintext
>>>-SysWaitNamedPipe(name=----------------++)------------------------><
 +-,timeout+-
```

Performs a timed wait on a named pipe and returns the WaitNamedPipe return code.

**Parameters:**

*name*

The name of the pipe in the form "\servername\pipe\pipename."

*timeout*

The number of microseconds to be waited. If you omit *timeout* or specify 0, SysWaitNamedPipe uses the default timeout value. To wait until the pipe is no longer busy, you can use a value of -1.

Returns 0 on success. A [Windows System Error code](#) is returned on error.
8.82. SysWinDecryptFile (Windows only)

```plaintext
>>>-SysWinDecryptFile(filename)---------------------------------><
```
Decrypts a given file (Windows 2000 only).

**Parameter:**

`filename`

The file to be decrypted.

**Return codes:**

0

Decryption was successful.

Other

A [Windows System Error code](http://www.example.com). This may be one of the following, but could be others.

2

File not found.

4

Cannot open file.

5

Access denied.

82

Cannot decrypt.

8.83. SysWinEncryptFile (Windows only)

```plaintext
>>>-SysWinEncryptFile(filename)---------------------------------><
```
Encrypts a given file (Windows 2000 only).

**Parameter:**

`filename`

The file to be encrypted.

**Return codes:**

0

Encryption was successful.
Chapter 8. Rexx Utilities (RexxUtil)

Other

A Windows System Error code. This may be one of the following, but could be others.

2
File not found.

4
Cannot open file.

5
Access denied.

82
Cannot encrypt.

8.84. SysWinGetDefaultPrinter (Windows only)

>>>-SysWinGetDefaultPrinter------------------------------------><

Returns the current default printer in the form "Printername,Drivername,Portname".

8.85. SysWinGetPrinters (Windows only)

>>>-SysWinGetPrinters(stem.)------------------------------------><

Fills a stem with the available printer descriptions.

Parameters:

stem.0
The number of entries

stem.i
Entry
Each entry is of the form "Printername,Drivername,Portname".

Return codes:

0
Success
Chapter 8. Rexx Utilities (RexxUtil)

Failure

8.86. SysWinSetDefaultPrinter (Windows only)

>>>-SysWinSetDefaultPrinter(description)<-

Sets the default printer.

Parameter:

description

A string identifying the printer. On Windows 2000 or later this string can be just the printer name. For earlier versions of Windows, the string must have the form "Printername,Drivername,Portname".

Note: For Windows 2000 or later either form of the description string is accepted. However, using just the printer name is the preferred method. Using the "Printername,Drivername,Portname" form will invoke an outdated Windows API that Microsoft has deprecated.

Return codes:

0

Success

non-zero

A Windows System Error code. You can use SysGetErrortext() to get a description of the error.

Example:

/* set default printer */

default = SysWinGetDefaultPrinter()
parsing var default default'"."
say 'The Default printer is: ' default
say

if SysWinGetPrinters(list.) == 0 then do
  say "List of available printers (* = default):"
do i=1 to list.0
  parsing var list.i pname"."
  if pname == default then
    say i list.i "*"
  else
    say i list.i
end
say
say "Please enter number of new default printer (0 = keep default)"
pull i

numberOk = .false

if i~datatype('W') then do
    if 0 <= i & i <= list.0 then do
        numberOk = .true
        if i > 0 then do
            /* Assumes we are on Windows 2000 or later. */
            parse var list.i pname",".
            ret = SysWinSetDefaultPrinter(pname)
            if ret <> 0 then do
                say "Error setting default printer ("ret"): " SysGetErrorText(ret)
            end
            else do
                say "The new default printer is:" pname
            end
        end
    end
if \\ numberOk then do
    say "You did not enter a valid printer number."
end
end do

8.87. SysWinVer Windows only)

>>-SysWinVer()------------------------------------------><

Returns a string specifying the Windows operating system version information in the form x.xx.
Chapter 9. Parsing

The parsing instructions are ARG, PARSE, and PULL (see ARG, PARSE, and PULL).

The data to be parsed is a source string. Parsing splits the data in a source string and assigns pieces of it to the variables named in a template. A template is a model specifying how to split the source string. The simplest kind of template consists of a list of variable names. Here is an example:

```
variable1 variable2 variable3
```

This kind of template parses the source string into whitespace-delimited words. More complicated templates contain patterns in addition to variable names:

String patterns

Match the characters in the source string to specify where it is to be split. (See Templates Containing String Patterns for details.)

Positional patterns

Indicate the character positions at which the source string is to be split. (See Templates Containing Positional (Numeric) Patterns for details.)

Parsing is essentially a two-step process:

1. Parse the source string into appropriate substrings using patterns.
2. Parse each substring into words.

9.1. Simple Templates for Parsing into Words

Here is a parsing instruction:

```
parse value "time and tide" with var1 var2 var3
```

The template in this instruction is: var1 var2 var3. The data to be parsed is between the keywords PARSE VALUE and the keyword WITH, the source string time and tide. Parsing divides the source string into whitespace-delimited words and assigns them to the variables named in the template as follows:

```
var1="time"
var2="and"
var3="tide"
```

In this example, the source string to be parsed is a literal string, time and tide. In the next example, the source string is a variable.

```
/* PARSE VALUE using a variable as the source string to parse */
string="time and tide"
parsed value string with var1 var2 var3 /* same results */
```
Chapter 9. Parsing

PARSE VALUE does not convert lowercase a-z in the source string to uppercase A-Z. If you want to convert characters to uppercase, use PARSE UPPER VALUE. See Using UPPER, LOWER, and CASELESS for a summary of the effect of parsing instructions on the case.

Note that if you specify the CASELESS option on a PARSE instruction, the string comparisons during the scanning operation are made independently of the alphabetic case. That is, a letter in uppercase is equal to the same letter in lowercase.

All of the parsing instructions assign the parts of a source string to the variables named in a template. There are various parsing instructions because of the differences in the nature or origin of source strings. For a summary of all the parsing instructions, see Parsing Instructions Summary.

The PARSE VAR instruction is similar to PARSE VALUE except that the source string to be parsed is always a variable. In PARSE VAR, the name of the variable containing the source string follows the keywords PARSE VAR. In the next example, the variable stars contains the source string. The template is star1 star2 star3.

```rexx
/* PARSE VAR example */
stars="Sirius Polaris Rigil"
parse var stars star1 star2 star3 /* star1="Sirius" */
/* star2="Polaris" */
/* star3="Rigil" */
```

All variables in a template receive new values. If there are more variables in the template than words in the source string, the leftover variables receive null (empty) values. This is true for the entire parsing: for parsing into words with simple templates and for parsing with templates containing patterns. Here is an example of parsing into words:

```rexx
/* More variables in template than (words in) the source string */
satellite="moon"
parse var satellite Earth Mercury /* Earth="moon" */
/* Mercury="" */
```

If there are more words in the source string than variables in the template, the last variable in the template receives all leftover data. Here is an example:

```rexx
/* More (words in the) source string than variables in template */
satellites="moon Io Europa Callisto..."
parse var satellites Earth Jupiter /* Earth="moon" */
/* Jupiter="Io Europa Callisto..." */
```

Parsing into words removes leading and trailing whitespace characters from each word before it is assigned to a variable. The exception to this is the word or group of words assigned to the last variable. The last variable in a template receives leftover data, preserving extra leading and trailing whitespace characters. Here is an example:

```rexx
/* Preserving extra blanks */
solar5="Mercury Venus Earth Mars Jupiter "
parse var solar5 var1 var2 var3 var4
/* var1 ="Mercury" */
/* var2 ="Venus" */
/* var3 ="Earth" */
/* var4 =" Mars Jupiter " */
```
Chapter 9. Parsing

In the source string, Earth has two leading blanks. Parsing removes both of them (the word-separator blank and the extra blank) before assigning var3="Earth". Mars has three leading blanks. Parsing removes one word-separator blank and keeps the other two leading blanks. It also keeps all five blanks between Mars and Jupiter and both trailing blanks after Jupiter.

Parsing removes no whitespace characters if the template contains only one variable. For example:

```
parse value " Pluto " with var1  /* var1=" Pluto ")
```

### 9.1.1. Message Term Assignments

In addition to assigning values to variables, the PARSE instruction also allows any message term value that can be used on the left side of an assignment instruction (See Assignments and Symbols). For example:

```
/* Preserving extra blanks */
solar5="Mercury Venus Earth Mars Jupiter 

d = .directory~new
parse var solar5 d~var1 d~var2 d~var3 d~var4
/* d~var1 ="Mercury" */
/* d~var2 ="Venus" */
/* d~var3 ="Earth" */
/* d~var4 =" Mars Jupiter " */
```

### 9.1.2. The Period as a Placeholder

A period in a template is a placeholder. It is used instead of a variable name, but it receives no data. It is useful as a "dummy variable" in a list of variables or to collect unwanted information at the end of a string. And it saves the overhead of unneeded variables.

The period in the first example is a placeholder. Be sure to separate adjacent periods with whitespace; otherwise, an error results.

```
/* Period as a placeholder */
stars="Arcturus Betelgeuse Sirius Rigil"
parse var stars . . brightest .  /* brightest="Sirius" */
/* Alternative to period as placeholder */
stars="Arcturus Betelgeuse Sirius Rigil"
parse var stars drop junk brightest rest  /* brightest="Sirius" */
```

### 9.2. Templates Containing String Patterns

A string pattern matches characters in the source string to indicate where to split it. A string pattern can be either of the following:
Literal string pattern

One or more characters within quotation marks.

Variable string pattern

A variable within parentheses with no plus (+), minus (-), or equal sign (=) before the left parenthesis. (See Parsing with Variable Patterns for details.)

Here are two templates, a simple template and a template containing a literal string pattern:

```ooRexx
var1 var2 /* simple template */
var1 ", " var2 /* template with literal string pattern */
```

The literal string pattern is: ", ". This template puts characters:

- From the start of the source string up to (but not including) the first character of the match (the comma) into var1
- Starting with the character after the last character of the match (the character after the blank that follows the comma) and ending with the end of the string into var2

A template with a string pattern can omit some of the data in a source string when assigning data to variables. The next two examples contrast simple templates with templates containing literal string patterns.

```ooRexx
/* Simple template */
name="Smith, John"
parse var name ln fn /* Assigns: ln="Smith," */
       /* fn="John" */
```

Notice that the comma remains (the variable ln contains "Smith,"). In the next example the template is ln ", " fn. This removes the comma.

```ooRexx
/* Template with literal string pattern */
name="Smith, John"
parse var name ln ", " fn /* Assigns: ln="Smith" */
       /* fn="John" */
```

First, the language processor scans the source string for ", ". It splits the source string at that point. The variable ln receives data starting with the first character of the source string and ending with the last character before the match. The variable fn receives data starting with the first character after the match and ending with the end of string.

A template with a string pattern omits data in the source string that matches the pattern. (There is a special case (see Combining String and Positional Patterns) in which a template with a string pattern does not omit matching data in the source string.) The pattern ", " (with a blank) is used instead of ", " (no blank) because, without the blank in the pattern, the variable fn receives " John" (including a blank).

If the source string does not contain a match for a string pattern, any variables preceding the unmatched string pattern get all the data in question. Any variables after that pattern receive the null string.

A null string is never found. It always matches the end of the source string.
9.3. Templates Containing Positional (Numeric) Patterns

A positional pattern is a number that identifies the character position at which the data in the source string is to be split. The number must be a whole number.

An absolute positional pattern is:

- A number with no plus (+) or minus (-) sign preceding it or with an equal sign (=) preceding it.
- An expression in parentheses with an equal sign before the left parenthesis. (See Parsing with Variable Patterns for details on variable positional patterns.)

The number specifies the absolute character position at which the source string is to be split.

Here is a template with absolute positional patterns:

```plaintext
variable1 11 variable2 21 variable3
```

The numbers 11 and 21 are absolute positional patterns. The number 11 refers to the 11th position in the input string, 21 to the 21st position. This template puts characters:

- 1 through 10 of the source string into `variable1`
- 11 through 20 into `variable2`
- 21 to the end into `variable3`

Positional patterns are probably most useful for working with a file of records, such as:

```
<table>
<thead>
<tr>
<th>Character positions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1      11  21   40</td>
</tr>
</tbody>
</table>
```

```
Fields: LASTNAME  FIRST  PSEUDONYM
```

The following example uses this record structure:

```plaintext
/* Parsing with absolute positional patterns in template */
record.1="Clemens Samuel Mark Twain "
record.2="Evans Mary Ann George Eliot "
record.3="Munro H.H. Saki "
do n=1 to 3
   parse var record.n lastname 11 firstname 21 pseudonym
   if lastname="Evans" & firstname="Mary Ann" then say "By George!"
end /* Says "By George!" after record 2 */
```

The source string is split at character position 11 and at position 21. The language processor assigns characters 1 to 10 to `lastname`, characters 11 to 20 to `firstname`, and characters 21 to 40 to `pseudonym`.

The template could have been:

```
1 lastname 11 firstname 21 pseudonym
```

instead of
Chapter 9. Parsing

```
lastname 11 firstname 21 pseudonym
```

Specifying 1 is optional.

Optionally, you can put an equal sign before a number in a template. An equal sign is the same as no sign before a number in a template. The number refers to a particular character position in the source string. These two templates are equal:

```
lastname 11 first 21 pseudonym
lastname =11 first =21 pseudonym
```

A relative positional pattern is a number with a plus (+) or minus (−) sign preceding it. It can also be a variable within parentheses, with a plus (+) or minus (−) sign preceding the left parenthesis; for details see Parsing with Variable Patterns.

The number specifies the relative character position at which the source string is to be split. The plus or minus indicates movement right or left, respectively, from the start of the string (for the first pattern) or from the position of the last match. The position of the last match is the first character of the last match. Here is the same example as for absolute positional patterns done with relative positional patterns:

```
/* Parsing with relative positional patterns in template */
record.1="Clemens Samuel Mark Twain "
record.2="Evans Mary Ann George Eliot "
record.3="Munro H.H. Saki "
do n=1 to 3
  parse var record.n lastname +10 firstname + 10 pseudonym
  If lastname="Evans" & firstname="Mary Ann" then say "By George!"
end /* same results */
```

Whitespace characters between the sign and the number are insignificant. Therefore, +10 and + 10 have the same meaning. Note that +0 is a valid relative positional pattern.

Absolute and relative positional patterns are interchangeable except in the special case (Combining String and Positional Patterns) when a string pattern precedes a variable name and a positional pattern follows the variable name. The templates from the examples of absolute and relative positional patterns give the same results.

```
<table>
<thead>
<tr>
<th>Implied starting point is position 1</th>
<th>lastname 11</th>
<th>lastname + 10</th>
<th>firstname 21</th>
<th>firstname + 10</th>
<th>pseudonym</th>
<th>pseudonym</th>
</tr>
</thead>
<tbody>
<tr>
<td>Put characters 1 through 10 in lastname. (non-inclusive stopping point is 11 (1 + 10))</td>
<td>Put characters 1 through 10 in firstname. (non-inclusive stopping point is 21 (11 + 10))</td>
<td>Put characters 21 through end of string in pseudonym.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

With positional patterns, a matching operation can back up to an earlier position in the source string. Here is an example using absolute positional patterns:

```
/* Backing up to an earlier position (with absolute positional) */
string="astronomers"
```
parse var string 2 var1 4 1 var2 2 4 var3 5 11 var4
say string "study" var1||var2||var3||var4
 /* Displays: "astronomers study stars" */

The absolute positional pattern 1 backs up to the first character in the source string.

With relative positional patterns, a number preceded by a minus sign backs up to an earlier position. Here is the same example using relative positional patterns:

/* Backing up to an earlier position (with relative positional) */
string="astronomers"
parse var string 2 var1 +2 -3 var2 +1 +2 var3 +1 +6 var4
say string "study" var1||var2||var3||var4 /* same results */

In the previous example, the relative positional pattern -3 backs up to the first character in the source string.

The templates in the previous two examples are equivalent.

<table>
<thead>
<tr>
<th>2</th>
<th>var1 4</th>
<th>1</th>
<th>var2 3</th>
<th>4 var3 5</th>
<th>11 var4</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>var2 +2</td>
<td>-3</td>
<td>var2 +1</td>
<td>+2 var3 +1</td>
<td>+6 var4</td>
</tr>
</tbody>
</table>

Start at 2.
Noninclusive stopping point is 4 (2 + 2 = 4).
Go to 1 (4-3=1).
Noninclusive stopping point is 2 (1+1=2).
Go to 4 (2+2=4).
Noninclusive stopping point is 5 (4+1=5).
Go to 11 (5+6=11).

You can use templates with positional patterns to make several assignments:

/* Making several assignments */
books="Silas Marner, Felix Holt, Daniel Deronda, Middlemarch"
parse var books 1 Eliot 1 Evans
 /* Assigns the (entire) value of books to Eliot and to Evans. */

A length positional pattern is a number with a (>) or (<) preceding it. It can also be an expression within parentheses, with a (>) or (<) preceding the left parenthesis; for details see Parsing with Variable Patterns.

The number specifies the length at which the source string is to be split, relative to the current position.. The > or < indicates movement right or left, respectively, from the start of the string (for the first pattern) or from the position of the last match. The position of the last match is the first character of the last match. Here is the same example as for relative positional patterns done with length positional patterns:

/* Parsing with relative positional patterns in template */
record.1="Clemens Samuel Mark Twain "
record.2="Evans Mary Ann George Eliot "
record.3="Munro H.H. Saki "
do n=1 to 3
parse var record.n lastname >10 firstname >10 pseudonym
If lastname="Evans" & firstname="Mary Ann" then say "By George!"
end /* same results */
Chapter 9. Parsing

Whitespace characters between the trigger and the number are insignificant. Therefore, >10 and > 10 have the same meaning. Note that >0 <0 and are valid length positional pattern.

The > length pattern and the + relative positional pattern are interchangeable except in the special case of the value 0. A >0 pattern will split the string into a null string and leave the match position unchanged. This is particularly useful for parsing off length-qualified fields from a string.

```/* Parsing with length patterns in template */
line = "04Mark0005Twain"
parse var line len +2 first >(len) len +2 middle >(len) len +2 last >(len)
say "'first' 'middle' 'last';" -- displays "Mark" "Twain"
/* parsing with relative patterns only */
parse var line len +2 first +(len) len +2 middle +(len) len +2 last +(len)
say "'first' 'middle' 'last';" -- displays "Mark" "05Twain" "Twain"
```

The < length pattern will move the position the indicated position to the left, and split the string between the original position and the movement position. At of the operation, the current position is returned to the original position. This movement is equivalent to using a negative relative pattern followed by a positive relative pattern for the same length. This operation allows for easy extraction of characters that precede a string match.

```/* Parsing with length patterns in template */
parse value '12345.6789' with '.' digit <1 -- digit -> "5"
/* parsing with relative patterns only */
parse value '12345.6789' with '.' -1 digit +1 -- digit -> "5"
```

9.3.1. Combining Patterns and Parsing into Words

If a template contains patterns that divide the source string into sections containing several words, string and positional patterns divide the source string into substrings. The language processor then applies a section of the template to each substring, following the rules for parsing into words.

```/* Combining string pattern and parsing into words */
name=" John Q. Public"
parse var name fn init "." ln /* Assigns: fn="John" */
/* init=" Q" */
/* ln=" Public" */
```

The pattern divides the template into two sections:

- fn init
- ln

The matching pattern splits the source string into two substrings:

- " John Q"
- " Public"
Chapter 9. Parsing

"Public"

The language processor parses these substrings into words based on the appropriate template section.

John has three leading blanks. All are removed because parsing into words removes leading and trailing blanks except from the last variable.

Q has six leading blanks. Parsing removes one word-separator blank and keeps the rest because init is the last variable in that section of the template.

For the substring "Public", parsing assigns the entire string into ln without removing any blanks. This is because ln is the only variable in this section of the template. (For details about treatment of whitespace characters, see Simple Templates for Parsing into Words.)

/* Combining positional patterns with parsing into words */
string="R E X X"
parse var string var1 var2 4 var3 6 var4 /* Assigns: var1="R" */
/* var2="E" */
/* var3=" X" */
/* var4=" X" */

The pattern divides the template into three sections:

* var1 var2
* var3
* var4

The matching patterns split the source string into three substrings that are individually parsed into words:

* "R E"
* " X"
* " X"

The variable var1 receives "R"; var2 receives "E". Both var3 and var4 receive " X" (with a blank before the X) because each is the only variable in its section of the template. (For details on treatment of whitespace characters, see Simple Templates for Parsing into Words.)

9.4. Parsing with Variable Patterns

You might want to specify a pattern by using the value of a variable or expression instead of a fixed string or number. You do this by placing an expression in parentheses. This is a variable reference. Whitespace characters are not necessary inside or outside the parentheses, but you can add them if you wish.

The template in the next parsing instruction contains the following literal string pattern ". ".

parse var name fn init ". " ln

Here is how to specify that pattern as a variable string pattern:

strngptrn=". "

ooRexx Reference Version 4.0.0 509
Chapter 9. Parsing

parse var name fn init (strngptrn) ln

If no equal, plus sign, minus sign, >, or < precedes the parenthesis that is before the variable name, the character string value of the variable is then treated as a string pattern. The expression can reference variables that have been set earlier in the same template.

Example:

/* Using a variable as a string pattern */
/* The variable (delim) is set in the same template */
SAY "Enter a date (mm/dd/yy format). =====> " /* assume 11/15/98 */
pull date
parse var date month 3 delim +1 day +2 (delim) year
/* Sets: month="11"; delim="/"; day="15"; year="98" */

If an equal, a plus, a minus sign, > or < precedes the left parenthesis, the value of the expression is treated as an absolute, relative positional, or length positional pattern. The value of the expression must be a positive whole number or zero.

The expression can reference variables that have been set earlier in the same template. In the following example, the first two fields specify the starting-character positions of the last two fields.

Example:

/* Using a variable as a positional pattern */
dataline = "12 26 .....Samuel ClemensMark Twain"
parse var dataline pos1 pos2 6 =(pos1) realtime =(pos2) pseudonym
/* Assigns: realtime="Samuel Clemens"; pseudonym="Mark Twain" */

The positional pattern 6 is needed in the template for the following reason: Word parsing occurs after the language processor divides the source string into substrings using patterns. Therefore, the positional pattern =(pos1) cannot be correctly interpreted as =12 until after the language processor has split the string at column 6 and assigned the blank-delimited words 12 and 26 to pos1 and pos2, respectively.

9.5. Using UPPER, LOWER, and CASELESS

Specifying UPPER on any of the PARSE instructions converts lowercase a-z to uppercase A-Z before parsing.

The ARG instruction is a short form of PARSE UPPER ARG. The PULL instruction is a short form of PARSE UPPER PULL. If you do not desire uppercase translation, use PARSE ARG instead of ARG or PARSE UPPER ARG, and PARSE PULL instead of PULL or PARSE UPPER PULL.

Specifying LOWER on any of the PARSE instructions converts uppercase A-Z to lowercase a-z before parsing.

Specifying CASELESS means the comparisons during parsing are independent of the case—that is, a letter in uppercase is equal to the same letter in lowercase.
9.6. Parsing Instructions Summary

All parsing instructions assign parts of the source string to the variables named in the template. The following table summarizes where the source string comes from.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Where the source string comes from</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARG</td>
<td>Arguments you list when you call the program or arguments in the call to a subroutine or function.</td>
</tr>
<tr>
<td>PARSE ARG</td>
<td>Arguments you list when you call the program or arguments in the call to a subroutine or function.</td>
</tr>
<tr>
<td>PARSE LINEIN</td>
<td>Next line in the default input stream.</td>
</tr>
<tr>
<td>PULL</td>
<td>The string at the head of the external data queue. (If the queue is empty, it uses default input, typically the terminal.)</td>
</tr>
<tr>
<td>PARSE PULL</td>
<td>The string at the head of the external data queue. (If the queue is empty, it uses default input, typically the terminal.)</td>
</tr>
<tr>
<td>PARSE SOURCE</td>
<td>System-supplied string giving information about the executing program.</td>
</tr>
<tr>
<td>PARSE VALUE</td>
<td>Expression between the keywords VALUE and WITH in the instruction.</td>
</tr>
<tr>
<td>PARSE VAR name</td>
<td>Parses the value of name.</td>
</tr>
<tr>
<td>PARSE VERSION</td>
<td>System-supplied string specifying the language, language level, and (three-word) date.</td>
</tr>
</tbody>
</table>

9.7. Parsing Instructions Examples

All examples in this section parse source strings into words.

ARG

/* ARG with source string named in Rexx program invocation */
/* Program name is PALETTE. Specify 2 primary colors (yellow, red, blue) on call. Assume call is: palette red blue */
arg var1 var2 /* Assigns: var1="RED"; var2="BLUE" */
If var1<"RED" & var1<"YELLOW" & var1<"BLUE" then signal err
If var2<"RED" & var2<"YELLOW" & var2<"BLUE" then signal err
total=length(var1)+length(var2)
SELECT;
  When total=7 then new="purple"
  When total=9 then new="orange"
  When total=10 then new="green"
Otherwise new=var1 /* entered duplicates */
END
Chapter 9. Parsing

Say new; exit  /* Displays: "purple" */

Err:
say 'Input error--color is not "red" or "blue" or "yellow"'; exit

ARG converts alphabetic characters to uppercase before parsing. An example of ARG with the arguments in the CALL to a subroutine is in Parsing Several Strings.

PARSE ARG is similar to ARG except that PARSE ARG does not convert alphabetic characters to uppercase before parsing.

PARSE LINEIN

parse linein "a=" num1 "c=" num2  /* Assume: 8 and 9 */
sum=num1+num2  /* Enter: a=8 b=9 as input */
say sum  /* Displays: "17" */

PARSE PULL

PUSH "80 7"  /* Puts data on queue */
parse pull fourscore seven  /* Assigns: fourscore="80"; seven="7" */
SAY fourscore+seven  /* Displays: "87" */

PARSE SOURCE

parse source sysname .
Say sysname  /* Possibly Displays: */
/* "Windows" */

PARSE VALUE.

PARSE VAR examples are throughout the chapter, starting with Parsing.

PARSE VERSION

parse version . level .
say level  /* Displays: "6.02" */

PULL is similar to PARSE PULL except that PULL converts alphabetic characters to uppercase before parsing.

9.8. Advanced Topics in Parsing

This section includes parsing several strings and flow charts illustrating a conceptual view of parsing.

9.8.1. Parsing Several Strings

Only ARG and PARSE ARG can have more than one source string. To parse several strings, you can specify several comma-separated templates. Here is an example:

parse arg template1, template2, template3
Chapter 9. Parsing

This instruction consists of the keywords PARSE ARG and three comma-separated templates. For an ARG instruction, the source strings to be parsed come from arguments you specify when you call a program or CALL a subroutine or function. Each comma is an instruction to the parser to move on to the next string.

Example:

/* Parsing several strings in a subroutine */
num="3"
musketeers="Porthos Athos Aramis D'Artagnan"
CALL Sub num,musketeers /* Passes num and musketeers to sub */
SAY total; say fourth /* Displays: "4" and " D'Artagnan" */
EXIT

Sub:
parse arg subtotal, . . . fourth
  total=subtotal+1
RETURN

Note that when a Rexx program is started as a command, only one argument string is recognized. You can pass several argument strings for parsing if:

- One Rexx program calls another Rexx program with the CALL instruction or a function call
- Programs written in other languages start a Rexx program

If there are more templates than source strings, each variable in a leftover template receives a null string. If there are more source strings than templates, the language processor ignores leftover source strings. If a template is empty (two subsequent commas) or contains no variable names, parsing proceeds to the next template and source string.

9.8.2. Combining String and Positional Patterns

There is a special case in which absolute and relative positional patterns do not work identically. Parsing with a template containing a string pattern skips the data in the source string that matches the pattern (see Templates Containing String Patterns). But a template containing the sequence string pattern, variable name, and relative position pattern does not skip the matching data. A relative positional pattern moves relative to the first character matching a string pattern. As a result, assignment includes the data in the source string that matches the string pattern.

/* Template containing string pattern, then variable name, then */
/* relative positional pattern does not skip any data. */
string="REstructured eXtended eXecutor"
parse var string var1 3 junk "X" var2 +1 junk "X" var3 +1 junk
say var1||var2||var3 /* Concatenates variables; displays: "Rexx" */

Here is how this template works:
9.8.3. Conceptual Overview of Parsing

The following figures are to help you understand the concept of parsing.

The figures include the following terms:

**string start**

is the beginning of the source string (or substring).

**string end**

is the end of the source string (or substring).

**length**

is the length of the source string.

**match start**

is in the source string and is the first character of the match.

**match end**

is in the source string. For a string pattern, it is the first character after the end of the match. For a positional pattern, it is the same as match start.

**match position**

is in the source string. For a string pattern, it is the first matching character. For a positional pattern, it is the position of the matching character.

**token**

is a distinct syntactic element in a template, such as a variable, a period, a pattern, or a comma.

**value**

is the numeric value of a positional pattern. This can be either a constant or the resolved value of a variable.
Figure 9-1. Conceptual Overview of Parsing

START
Token is first one in template.
Length=length(source string)
Match start=1
Match end=1

End of template?

yes → Parsing complete.

no → CALL Find Next Pattern.

CALL Word Parsing.

Skip to next token.

Token a comma?

yes → Set next source string and template.

no
Figure 9-3. Conceptual View of Word Parsing

START:
Match end of string start?
  yes
  String end = length + 1
  no
  String end = match start

Substring = substr(source string, string start, (string end – string start))
Token = previous pattern

Any more tokens?
  no
  Return
  yes
  Step to next token?
    no
    Token variable, message term, or period?
      no
      Any more tokens?
        no
        Next token a variable, message term, or period?
          no
          Assign rest of substring
          yes
          Assign null string
        yes
        Any substring left?
          no
          Assign null string
          yes
          Strip any leading blanks

Any substring left?
  no
  Assign null string
  yes
  Blank found in substring?
    no
    Assign rest of substring
    yes
  Assign word from substring and step past blank

Note: The figures do not include error cases.
Chapter 10. Numbers and Arithmetic

This chapter gives an overview of the arithmetic facilities of the Rexx language.

Numbers can be expressed flexibly. Leading and trailing whitespace characters are permitted, and exponential notation can be used. Valid numbers are, for example:

```
12    /* a whole number */
"-76"    /* a signed whole number */
12.76    /* decimal places */
" + 0.003 "  /* blanks around the sign and so forth */
17.    /* same as 17 */
.5    /* same as 0.5 */
4E9    /* exponential notation */
0.73e-7    /* exponential notation */
```

A number in Rexx is defined as follows:

```
>>-+------------+--+----------------------+--+-digits--------+--------->
| whitespace-+ | sign |------------| + | digits.digits-|
| whitespace-+ | .digits-----|
| digits.-------|

>--+------------+--------------------------------------------------><
| whitespace-+|
```

**whitespace**

are one or more blanks or horizontal tab characters.

**sign**

is either + or -.

**digits**

are one or more of the decimal digits 0-9.

Note that a single period alone is not a valid number.

The arithmetic operators include addition (+), subtraction (-), multiplication (*), power (**), division (/), prefix plus (+), and prefix minus (-). In addition, it includes integer divide (%), which divides and returns the integer part, and remainder (/), which divides and returns the remainder. For examples of the arithmetic operators, see Operator Examples.

The result of an arithmetic operation is formatted as a character string according to specific rules. The most important rules are:

- Results are calculated up to a maximum number of significant digits. The default is 9, but can be overridden on a source-file basis with the ::OPTIONS directive. For 64-bit systems, the default setting can be altered with the NUMERIC DIGITS instruction. Thus, with NUMERIC DIGITS 9, if a result requires more than 9 digits, it is rounded to 9 digits. For example, the division of 2 by 3 results in 0.666666667.
Chapter 10. Numbers and Arithmetic

- Except for division and power, trailing zeros are preserved. For example:
  
  \[ \begin{align*}
  2.40 + 2 & \rightarrow 4.40 \\
  2.40 - 2 & \rightarrow 0.40 \\
  2.40 \times 2 & \rightarrow 4.80 \\
  2.40 \div 2 & \rightarrow 1.2 
  \end{align*} \]

  If necessary, you can remove trailing zeros with the STRIP method (see STRIP), the STRIP function (see STRIP), or by division by 1.

- A zero result is always expressed as the single digit 0.

- Exponential form is used for a result depending on its value and the setting of NUMERIC DIGITS. If the number of places needed before the decimal point exceeds the NUMERIC DIGITS setting, or the number of places after the point exceeds twice the NUMERIC DIGITS setting, the number is expressed in exponential notation:

  \[ \begin{align*}
  1e6 \times 1e6 & \rightarrow 1E+12 /* not 1000000000000 */ \\
  1 \div 3E10 & \rightarrow 3.33333333E-11 /* not 0.0000000000333333333 */ 
  \end{align*} \]

10.1. Precision

Precision is the maximum number of significant digits that can result from an operation. This is controlled by the instruction:

\[ \begin{array}{l}
\text{>>-NUMERIC DIGITS-+-+-+-+;---------------------------><} \\
\text{+-expression+-} 
\end{array} \]

The expression is evaluated and must result in a positive whole number. This defines the precision (number of significant digits) of a calculation. Results are rounded to that precision, if necessary.

If you do not specify expression in this instruction, or if no NUMERIC DIGITS instruction has been processed since the start of a program, the default precision is used. The Rexx standard for the default precision is 9. The default may be overridden on a source-file basis using the ::OPTIONS directive.

NUMERIC DIGITS can set values smaller than nine. However, use small values with care because the loss of precision and rounding affects all Rexx computations, including, for example, the computation of new values for the control variable in DO loops.

10.2. Arithmetic Operators

Rexx arithmetic is performed by the operators +, -, *, /, \%, //, and ** (add, subtract, multiply, divide, integer divide, remainder, and power).

Before every arithmetic operation, the terms operated upon have leading zeros removed (noting the position of any decimal point, and leaving only one zero if all the digits in the number are zeros). They are then truncated, if necessary, to DIGITS + 1 significant digits before being used in the computation.

The extra digit improves accuracy because it is inspected at the end of an operation, when a number is rounded to the required precision. When a number is truncated, the LOSTDIGITS condition is raised if a SIGNAL ON LOSTDIGITS condition trap is active. The operation is then carried out under up to double that precision. When the operation is completed, the result is rounded, if necessary, to the precision specified by the NUMERIC DIGITS instruction.
Chapter 10. Numbers and Arithmetic

The values are rounded as follows: 5 through 9 are rounded up, and 0 through 4 are rounded down.

10.2.1. Power

The ** (power) operator raises a number to a power, which can be positive, negative, or 0. The power must be a whole number. The second term in the operation must be a whole number and is rounded to DIGITS digits, if necessary, as described under Limits and Errors when Rexx Uses Numbers Directly. If negative, the absolute value of the power is used, and the result is inverted (that is, the number 1 is divided by the result). For calculating the power, the number is multiplied by itself for the number of times expressed by the power. Trailing zeros are then removed as though the result were divided by 1.

10.2.2. Integer Division

The % (integer divide) operator divides two numbers and returns the integer part of the result. The result is calculated by repeatedly subtracting the divisor from the dividend as long as the dividend is larger than the divisor. During this subtraction, the absolute values of both the dividend and the divisor are used: the sign of the final result is the same as that which would result from regular division.

If the result cannot be expressed as a whole number, the operation is in error and fails—that is, the result must not have more digits than the current setting of NUMERIC DIGITS. For example, 10000000000%3 requires 10 digits for the result (3333333333) and would, therefore, fail if NUMERIC DIGITS 9 were in effect.

10.2.3. Remainder

The // (remainder) operator returns the remainder from an integer division and is defined to be the residue of the dividend after integer division. The sign of the remainder, if nonzero, is the same as that of the original dividend.

This operation fails under the same conditions as integer division, that is, if integer division on the same two terms fails, the remainder cannot be calculated.

10.2.4. Operator Examples

/* With: NUMERIC DIGITS 5 */
12+7.00  ->  19.00
1.3-1.07 ->  0.23
1.3-2.07 -> -0.77
1.20*3   ->  3.60
7*3      ->  21
0.9*0.8  ->  0.72
1/3      ->  0.33333
2/3      ->  0.66667
5/2      ->   2.5
1/10     ->   0.1
12/12    ->    1
### 10.3. Exponential Notation

For both large and small numbers, an exponential notation can be useful. For example:

```rexx
class def number
  numeric digits 5
  say 54321*54321
end class
```

would display `2950800000` in the long form. Because this is misleading, the result is expressed as `2.9508E+9` instead.

The definition of numbers is, therefore, extended as follows:

```rexx
>>+-+-----------------------------+-------------------------><
   +whitespace-+ +sign--+-digits-----+  +-digits+-
   +whitespace-+   +-digits------+
   +whitespace-+   +-digits------+
   +-E--+------+--digits-+ +-whitespace-+  +-sign-+ 
```

The integer following the \(E\) represents a power of ten that is to be applied to the number. The \(E\) can be in uppercase or lowercase.

Certain character strings are numbers even though they do not appear to be numeric, such as `0E123` (0 raised to the 123 power) and `1E342` (1 raised to the 342 power). Also, a comparison such as `0E123=0E567` gives a true result of 1 (0 is equal to 0). To prevent problems when comparing nonnumeric strings, use the strict comparison operators.

Here are some examples:

```rexx
12E7   =  120000000 /* Displays "1" */
12E-5  =  0.00012 /* Displays "1" */
-12e4  =  -120000 /* Displays "1" */
0e123  =  0e456 /* Displays "1" */
0e123  ==  0e456 /* Displays "0" */
```

522  ooRexx Reference Version 4.0.0
Chapter 10. Numbers and Arithmetic

The results of calculations are returned in either conventional or exponential form, depending on the setting of NUMERIC DIGITS. If the number of places needed before the decimal point exceeds DIGITS, or the number of places after the point exceeds twice DIGITS, the exponential form is used. The exponential form the language processor generates always has a sign following the E to improve readability. If the exponent is 0, the exponential part is omitted—that is, an exponential part of E+0 is not generated.

You can explicitly convert numbers to exponential form, or force them to be displayed in the long form, by using the FORMAT built-in function (see FORMAT).

Scientific notation is a form of exponential notation that adjusts the power of ten so that the number contains only one nonzero digit before the decimal point. Engineering notation is a form of exponential notation in which up to three digits appear before the decimal point, and the power of ten is always a multiple of three. The integer part can, therefore, range from 1 through 999. You can control whether scientific or engineering notation is used with the following instruction:

+-SCIENTIFIC---------------+
>>-NUMERIC FORM--+-expression-+-VALUE-<
+-ENGINEERING-----------+
+-+-------+--expression-+
  +-VALUE-+

Scientific notation is the default.

/* after the instruction */
Numeric form scientific

123.45 * 1e11  ->  1.2345E+13

/* after the instruction */
Numeric form engineering

123.45 * 1e11  ->  12.345E+12

10.4. Numeric Comparisons

The comparison operators are listed in Comparison. You can use any of them for comparing numeric strings. However, you should not use =, \=, -==, >>, \>>, -=>>, <<, \<<, and -=<< for comparing numbers because leading and trailing whitespace characters and leading zeros are significant with these operators.

Numeric values are compared by subtracting the two numbers (calculating the difference) and then comparing the result with 0. That is, the operation:

A ? Z

where ? is any numeric comparison operator, is identical with:

(A - Z) ? "0"
Chapter 10. Numbers and Arithmetic

It is, therefore, the difference between two numbers, when subtracted under Rexx subtraction rules, that determines their equality.

Fuzz affects the comparison of two numbers. It controls how much two numbers can differ and still be considered equal in a comparison. The FUZZ value is set by the following instruction:

```
>>-NUMERIC FUZZ--+-expression-+-;-----------------------------><
```

(expression) must result in a positive whole number or zero. The default is 0.

Fuzz is to temporarily reduce the value of DIGITS. That is, the numbers are subtracted with a precision of DIGITS minus FUZZ digits during the comparison. The FUZZ setting must always be less than DIGITS.

If, for example, DIGITS = 9 and FUZZ = 1, the comparison is carried out to 8 significant digits, just as though NUMERIC DIGITS 8 had been put in effect for the duration of the operation.

Example:

```
Numeric digits 5
Numeric fuzz 0
say 4.9999 = 5 /* Displays "0" */
say 4.9999 < 5 /* Displays "1" */
Numeric fuzz 1
say 4.9999 = 5 /* Displays "1" */
say 4.9999 < 5 /* Displays "0" */
```

10.5. Limits and Errors when Rexx Uses Numbers Directly

When Rexx uses numbers directly, that is, numbers that have not been involved in an arithmetic operation, they are rounded, if necessary, according to the setting of NUMERIC DIGITS. The normal whole number limit depends on the platform default NUMERIC DIGITS setting. If the default setting is 9, the whole number limit is 999999999. If the default DIGITS value is 18, the whole number limit is 999999999999999999.

The following table shows which numbers must be whole numbers and what their limits are:

<table>
<thead>
<tr>
<th>Table 10-1. Whole Number Limits</th>
</tr>
</thead>
<tbody>
<tr>
<td>Power values (right-hand operand of the power operator)</td>
</tr>
<tr>
<td>Values of expr and exprf in the DO instruction</td>
</tr>
<tr>
<td>Values given for DIGITS or FUZZ in the NUMERIC instruction</td>
</tr>
<tr>
<td>Positional patterns in parsing templates</td>
</tr>
<tr>
<td>Number given for option in the TRACE instruction</td>
</tr>
</tbody>
</table>
When Rexx uses numbers directly, the following types of errors can occur:

- **Overflow or underflow.**
  
  This error occurs if the exponential part of a result exceeds the range that the language processor can handle, when the result is formatted according to the current settings of NUMERIC DIGITS and NUMERIC FORM. The language defines a minimum capability for the exponential part, namely the largest number that can be expressed as an exact integer in default precision. Because the default precision is 9, you can use exponents in the range -999999999 through 999999999.

  Because this allows for (very) large exponents, overflow or underflow is treated as a syntax error.

- **Insufficient storage.**

  Storage is needed for calculations and intermediate results, and if an arithmetic operation fails because of lack of storage. This is considered as a terminating error.
Chapter 11. Conditions and Condition Traps

A condition is an event or state that CALL ON or SIGNAL ON can trap. A condition trap can modify the flow of execution in a Rexx program. Condition traps are turned on or off using the ON or OFF subkeywords of the SIGNAL and CALL instructions (see CALL and SIGNAL).

>>++CALL--------------------------->
 | +SIGNAL++

>---OFF----condition----------------<
  | +-USER--usercondition++
  | +ON---condition--------------++
  | +USER--usercondition++ +NAME--trapname++

condition, usercondition, and trapname are single symbols that are taken as constants. Following one of these instructions, a condition trap is set to either ON (enabled) or OFF (disabled). The initial setting for all condition traps is OFF.

If a condition trap is enabled and the specified condition or usercondition occurs, control passes to the routine or label trapname if you have specified trapname. Otherwise, control passes to the routine or label usercondition or condition. CALL or SIGNAL is used, depending on whether the most recent trap for the condition was set using CALL ON or SIGNAL ON, respectively.

Note: If you use CALL, the trapname can be an internal label, a built-in function, or an external routine. If you use SIGNAL, the trapname can only be an internal label.

The conditions and their corresponding events that can be trapped are:

ANY
traps any condition that a more specific condition trap does not trap. For example, if NOVALUE is raised and there is no NOVALUE trap enabled, but there is a SIGNAL ON ANY trap, the ANY trap is called for the NOVALUE condition. For example, a CALL ON ANY trap is ignored if NOVALUE is raised because CALL ON NOVALUE is not allowed.

ERROR
raised if a command indicates an error condition upon return. It is also raised if any command indicates failure and none of the following is active:

• CALL ON FAILURE
• SIGNAL ON FAILURE
• CALL ON ANY
• SIGNAL ON ANY

The condition is raised at the end of the clause that called the command but is ignored if the ERROR condition trap is already in the delayed state. The delayed state is the state of a condition trap when the condition has been raised but the trap has not yet been reset to the enabled (ON) or disabled (OFF) state.
Chapter 11. Conditions and Condition Traps

FAILURE

raised if a command indicates a failure condition upon return. The condition is raised at the end of the clause that called the command but is ignored if the FAILURE condition trap is already in the delayed state.

An attempt to enter a command to an unknown subcommand environment also raises a FAILURE condition.

HALT

raised if an external attempt is made to interrupt and end execution of the program. The condition is usually raised at the end of the clause that was processed when the external interruption occurred.

When a Rexx program is running in a full-screen or command prompt session, the Ctrl+Break key combination raises the halt condition. However, if Ctrl+Break is pressed while a command or non-Rexx external function is processing, the command or function ends.

Notes:

1. Application programs that use the Rexx language processor might use the RXHALT exit or the RexxStart programming interface to halt the execution of a Rexx macro. (See the Open Object Rexx: Programming Guide for details about exits.)

2. Only SIGNAL ON HALT or CALL ON HALT can trap error 4, described in Appendix C. Error Numbers and Messages.

LOSTDIGITS

raised if a number used in an arithmetic operation has more digits than the current setting of NUMERIC DIGITS. Leading zeros are not counted in this comparison. You can specify the LOSTDIGITS condition only for SIGNAL ON.

NOMETHOD

raised if an object receives a message for which it has no method defined, and the object does not have an UNKNOWN method. You can specify the NOMETHOD condition only for SIGNAL ON.

NOSTRING

raised when the language processor requires a string value from an object and the object does not directly provide a string value. See Required String Values for more information. You can specify the NOSTRING condition only for SIGNAL ON.

NOTREADY

raised if an error occurs during an input or output operation. See Errors during Input and Output. This condition is ignored if the NOTREADY condition trap is already in the delayed state.

NOVALUE

raised if an uninitialized variable is used as:

• A term in an expression

• The name following the VAR subkeyword of a PARSE instruction
• A variable reference in a parsing template, an EXPOSE instruction, a PROCEDURE instruction, or a DROP instruction
• A method selection override specifier in a message term

**Note:** SIGNAL ON NOVALUE can trap any uninitialized variables except tails in compound variables.

```plaintext
/* The following does not raise NOVALUE. */
signal on novalue
a.=0
say a.z
say "NOVALUE is not raised."
exit

novalue:
say "NOVALUE is raised."
You can specify this condition only for SIGNAL ON.
```

**SYNTAX**

raised if any language-processing error is detected while the program is running. This includes all kinds of processing errors:

• True syntax errors
• "Run-time" errors (such as attempting an arithmetic operation on nonnumeric terms)
• Syntax errors propagated from higher call or method invocation levels
• Untrapped HALT conditions
• Untrapped NOMETHOD conditions

You can specify this condition only for SIGNAL ON.

**Notes:**

1. SIGNAL ON SYNTAX cannot trap the errors 3 and 5.
2. SIGNAL ON SYNTAX can trap the errors 6 and 30 only if they occur during the execution of an INTERPRET instruction.

For information on these errors, refer to Error Numbers and Messages.

**USER**

raised if a condition specified on the USER option of CALL ON or SIGNAL ON occurs. USER conditions are raised by a RAISE instruction that specifies a USER option with the same usercondition name. The specified usercondition can be any symbol, including those specified as possible values for condition.

Any ON or OFF reference to a condition trap replaces the previous state (ON, OFF, or DELAY, and any trapname) of that condition trap. Thus, a CALL ON HALT replaces any current SIGNAL ON HALT (and a SIGNAL ON HALT replaces any current CALL ON HALT), a CALL ON or SIGNAL ON with a new trap name replaces any previous trap name, and any OFF reference disables the trap for CALL or SIGNAL.
11.1. Action Taken when a Condition Is Not Trapped

When a condition trap is currently disabled (OFF) and the specified condition occurs, the default action depends on the condition:

- For HALT and NOMETHOD, a SYNTAX condition is raised with the appropriate Rexx error number.
- For SYNTAX conditions, the clause in error is terminated, and a SYNTAX condition is propagated to each CALL instruction, INTERPRET instruction, message instruction, or clause with function or message invocations active at the time of the error, terminating each instruction if a SYNTAX trap is not active at the instruction level. If the SYNTAX condition is not trapped at any of the higher levels, processing stops, and a message (see Error Numbers and Messages) describing the nature of the event that occurred usually indicates the condition.
- For all other conditions, the condition is ignored and its state remains OFF.

11.2. Action Taken when a Condition Is Trapped

When a condition trap is currently enabled (ON) and the specified condition occurs, a CALL trapname or SIGNAL trapname instruction is processed automatically. You can specify the trapname after the NAME subkeyword of the CALL ON or SIGNAL ON instruction. If you do not specify a trapname, the name of the condition itself (for example, ERROR or FAILURE) is used.

For example, the instruction call on error enables the condition trap for the ERROR condition. If the condition occurred, then a call to the routine identified by the name ERROR is made. The instruction call on error name commanderror would enable the trap and call the routine COMMANDERROR if the condition occurred, and the caller usually receives an indication of failure.

The sequence of events, after a condition has been trapped, varies depending on whether a SIGNAL or CALL is processed:

- If the action taken is a SIGNAL, execution of the current instruction ceases immediately, the condition is disabled (set to OFF), and SIGNAL proceeds as usually (see SIGNAL).
  
  If any new occurrence of the condition is to be trapped, a new CALL ON or SIGNAL ON instruction for the condition is required to re-enable it when the label is reached. For example, if SIGNAL ON SYNTAX is enabled when a SYNTAX condition occurs, a usual syntax error termination occurs if the SIGNAL ON SYNTAX label name is not found.

- If the action taken is a CALL, the call trapname proceeds in the usual way (see CALL) when the instruction completes. The call does not affect the special variable RESULT. If the routine should RETURN any data, that data is ignored.

  When the condition is raised, and before the CALL is made, the condition trap is put into a delayed state. This state persists until the RETURN from the CALL, or until an explicit CALL (or SIGNAL) ON (or OFF) is made for the condition. This delayed state prevents a premature condition trap at the start of the routine called to process a condition trap. When a condition trap is in the delayed state, it remains enabled, but if the condition is raised again, it is either ignored (for ERROR and FAILURE) or (for the other conditions) any action (including the updating of the condition information) is delayed until one of the following events occurs:
Chapter 11. Conditions and Condition Traps

1. A CALL ON or SIGNAL ON for the delayed condition is processed. In this case, a CALL or SIGNAL takes place immediately after the new CALL ON or SIGNAL ON instruction has been processed.

2. A CALL OFF or SIGNAL OFF for the delayed condition is processed. In this case, the condition trap is disabled and the default action for the condition occurs at the end of the CALL OFF or SIGNAL OFF instruction.

3. A RETURN is made from the subroutine. In this case, the condition trap is no longer delayed and the subroutine is called again immediately.

On RETURN from the CALL, the original flow of execution is resumed, that is, the flow is not affected by the CALL.

Notes:

1. In all cases, the condition is raised immediately upon detection. If SIGNAL ON traps the condition, the current instruction is ended, if necessary. Therefore, the instruction during which an event occurs can only be partly processed. For example, if SYNTAX is raised during the evaluation of the expression in an assignment, the assignment does not take place. Note that the CALL for traps for which CALL ON is enabled can only occur at clause boundaries. If these conditions arise in the middle of an INTERPRET instruction, execution of INTERPRET can be interrupted and resumed later. Similarly, other instructions, for example DO or SELECT, can be temporarily interrupted by a CALL at a clause boundary.

2. The state (ON, OFF, or DELAY, and any trapname) of each condition trap is saved on entry to a subroutine and is then restored on RETURN. This means that CALL ON, CALL OFF, SIGNAL ON, and SIGNAL OFF can be used in a subroutine without affecting the conditions set up by the caller. See CALL for details of other information that is saved during a subroutine call.

3. The state of condition traps is not affected when an external routine is called by a CALL, even if the external routine is a Rexx program. On entry to any Rexx program, all condition traps have an initial setting of OFF.

4. While user input is processed during interactive tracing, all condition traps are temporarily set OFF. This prevents any unexpected transfer of control—e.g., should the user accidentally use an uninitialized variable while SIGNAL ON NOVALUE is active. For the same reason, a syntax error during interactive tracing does not cause the exit from the program but is trapped specially and then ignored after a message is given.

5. The system interface detects certain execution errors either before the execution of the program starts or after the program has ended. SIGNAL ON SYNTAX cannot trap these errors.

Note that a label is a clause consisting of a single symbol followed by a colon. Any number of successive clauses can be labels; therefore, several labels are allowed before another type of clause.

11.3. Condition Information

When a condition is trapped and causes a SIGNAL or CALL, this becomes the current trapped condition, and certain condition information associated with it is recorded. You can inspect this information by using the CONDITION built-in function (see CONDITION).

The condition information includes:
• The name of the current trapped condition
• The name of the instruction processed as a result of the condition trap (CALL or SIGNAL)
• The status of the trapped condition
• A descriptive string (see Descriptive Strings) associated with that condition
• Optional additional object information (see Additional Object Information)

The current condition information is replaced when control is passed to a label as the result of a condition trap (CALL ON or SIGNAL ON). Condition information is saved and restored across subroutine or function calls, including one because of a CALL ON trap and across method invocations. Therefore, a routine called by CALL ON can access the appropriate condition information. Any previous condition information is still available after the routine returns.

11.3.1. Descriptive Strings

The descriptive string varies, depending on the condition trapped:

ERROR
The string that was processed and resulted in the error condition.

FAILURE
The string that was processed and resulted in the failure condition.

HALT
Any string associated with the halt request. This can be the null string if no string was provided.

LOSTDIGITS
The number with excessive digits that caused the LOSTDIGITS condition.

NOMETHOD
The name of the method that could not be found.

NOSTRING
The readable string representation of the object causing the NOSTRING condition.

NOTREADY
The name of the stream being manipulated when the error occurred and the NOTREADY condition was raised. If the stream was a default stream with no defined name, then the null string might be returned.

NOVALUE
The derived name of the variable whose attempted reference caused the NOVALUE condition.
Chapter 11. Conditions and Condition Traps

SYNTAX

Any string the language processor associated with the error. This can be the null string if you did not provide a specific string. Note that the special variables RC and SIGL provide information on the nature and position of the processing error. You can enable the SYNTAX condition trap only by using SIGNAL ON.

USER

Any string specified by the DESCRIPTION option of the RAISE instruction that raised the condition. If a description string was not specified, a null string is used.

11.3.2. Additional Object Information

The language processor can provide additional information, depending on the condition trapped:

NOMETHOD

The object that raised the NOMETHOD condition.

NOSTRING

The object that caused the NOSTRING condition.

NOTREADY

The stream object that raised the NOTREADY condition.

SYNTAX

An array containing the objects substituted into the secondary error message (if any) for the syntax error. If the message did not contain substitution values, a zero element array is used.

USER

Any object specified by an ADDITIONAL or ARRAY option of the RAISE instruction that raised the condition.

11.3.3. The Special Variable RC

When an ERROR or FAILURE condition is trapped, the Rexx special variable RC is set to the command return code before control is transferred to the target label (whether by CALL or by SIGNAL).

Similarly, when SIGNAL ON SYNTAX traps a SYNTAX condition, the special variable RC is set to the syntax error number before control is transferred to the target label.

11.3.4. The Special Variable SIGL

Following any transfer of control because of a CALL or SIGNAL, the program line number of the clause causing the transfer of control is stored in the special variable SIGL. If the transfer of control is because of a condition trap, the line number assigned to SIGL is that of the last clause processed (at the current
Chapter 11. Conditions and Condition Traps

subroutine level) before the CALL or SIGNAL took place. The setting of SIGL is especially useful after a SIGNAL ON SYNTAX trap when the number of the line in error can be used, for example, to control a text editor. Typically, code following the SYNTAX label can PARSE SOURCE to find the source of the data and then call an editor to edit the source file, positioned at the line in error. Note that in this case you might have to run the program again before any changes made in the editor can take effect.

Alternatively, SIGL can help determine the cause of an error (such as the occasional failure of a function call) as in the following example:

```rexx
signal on syntax
a = a + 1     /* This is to create a syntax error */
say "SYNTAX error not raised"
exit

/* Standard handler for SIGNAL ON SYNTAX */
syntax:
say "Rexx error" rc "in line" sigl:" "ERRORTEXT"(rc)
say "SOURCeline"(sigl)
trace ?r; nop
```

This code first displays the error code, line number, and error message. It then displays the line in error, and finally drops into debug mode to let you inspect the values of the variables used at the line in error.

11.3.5. Condition Objects

A condition object is a directory returned by the Object option of the CONDITION built-in function. This directory contains all information currently available on a trapped condition. The information varies with the trapped condition. The Nil object is returned for any entry not available to the condition. The following entries can be found in a condition object:

**ADDITIONAL**

The additional information object associated with the condition. This is the same object that the Additional option of the CONDITION built-in function returns. The ADDITIONAL information may be specified with the ADDITIONAL or ARRAY options of the RAISE instruction.

**DESCRIPTION**

The string describing the condition. The Description option of the CONDITION built-in function also returns this value.

**INSTRUCTION**

The keyword for the instruction executed when the condition was trapped, either CALL or SIGNAL. The Instruction option of the CONDITION built-in function also returns this value.

**CONDITION**

The name of the trapped condition. The Condition name option of the CONDITION built-in function also returns this value.
RESULT
Any result specified on the RETURN or EXIT options of a RAISE instruction.

RC
The major Rexx error number for a SYNTAX condition. This is the same error number assigned to the special variable RC.

CODE
The detailed identification of the error that caused a SYNTAX condition. This number is a nonnegative number in the form nn.nnn. The integer portion is the Rexx major error number (the same value as the RC entry). The fractional portion is a subcode that gives a precise indication of the error that occurred.

ERRORTEXT
The primary error message for a SYNTAX condition. This is the same message available from the ERRORTEXT built-in function.

MESSAGE
The secondary error message for a SYNTAX condition. The message also contains the content of the ADDITIONAL information.

PACKAGE
The Package object associated with the program where a syntax condition was raised.

POSITION
The line number in source code at which a SYNTAX condition was raised.

PROGRAM
The name of the program where a SYNTAX condition was raised.

TRACEBACK
A single-index list of formatted traceback lines.

PROPAGATED
The value 0 (false) if the condition was raised at the same level as the condition trap or the value 1 (true) if the condition was reraised with RAISE PROPAGATE.
Chapter 11. Conditions and Condition Traps
Chapter 12. Concurrency

Conceptually, each Rexx object is like a small computer with its own processor to run its methods, its memory for object and method variables, and its communication links to other objects for sending and receiving messages. This is object-based concurrency. It lets more than one method run at the same time. Any number of objects can be active (running) at the same time, exchanging messages to communicate with, and synchronize, each other.

12.1. Early Reply

Early reply provides concurrent processing. A running method returns control, and possibly a result, to the point from which it was called; meanwhile it continues running. The following figure illustrates this concept.

Figure 12-1. Early Reply

Method A includes a call to Method B. Method B contains a REPLY instruction. This returns control and a result to method A, which continues processing with the line after the call to Method B. Meanwhile, Method B also continues running.

The chains of execution represented by method A and method B are called activities. An activity is a thread of execution that can run methods concurrently with methods on other activities.

An activity contains a stack of invocations that represent the Rexx programs running on the activity. An invocation can be a main program invocation, an internal function or subroutine call, an external function or subroutine call, an INTERPRET instruction, or a message invocation. An invocation is activated when an executable unit is invoked and removed (popped) when execution completes. In the Early Reply figure, the programs begins with a single activity. The activity contains a single invocation, method A. When method A invokes method B, a second invocation is added to the activity.

When method B issues a REPLY, a new activity is created (activity 2). Method B’s invocation is removed from activity 1, and pushed on to activity 2. Because activities can execute concurrently, both method A and method B continue processing. The following figures illustrate this concept.
Here is an example of using early reply to run methods concurrently.

/* Example of early reply */

object1 = .example/new
object2 = .example/new

say object1\nrepeat(10, "Object 1 running")
say object2\nrepeat(10, "Object 2 running")
say "Main ended."
12.2. Message Objects

A message object (see The Message Class) is an intermediary between two objects that enables concurrent processing. All objects inherit the START method (see the Message Class) from the object class. To obtain a message object, an object sends a START message to the object to which the message object will convey a message. The message is an argument to the START message as in the following example:

```
a=p~start(“REVERSE”)
```

This line of code creates a message object, **a**, and sends it a start message. The message object then sends the REVERSE message to object **p**. Object **p** receives the message, performs any needed processing, and returns a result to message object **a**. Meanwhile the object that obtained message object **a** continues its processing. When message object **a** returns, it does not interrupt the object that obtained it. It waits until this object requests the information. Here is an example of using a message object to run methods concurrently.

```
/* Example of using a message object */

object1 = .example~new
object2 = .example~new

a = object1~start(“REPEAT”,10,”Object 1 running”)
b = object2~start(“REPEAT”,10,”Object 2 running”)

say a~result
say b~result
say ”Main ended.”
exit
```

```
::class example
::method repeat
use arg reps, msg
reply ”Repeating” msg”,” reps ”times.”
do reps
  say msg
end
return ”Repeated” msg”,” reps ”times.”
```
12.3. Default Concurrency

The instance methods of a class use the EXPOSE instruction to define a set of object variables. This collection of variables belonging to an object is called its object variable pool. The methods a class defines and the variables these methods can access is called a scope. Rexx’s default concurrency exploits the idea of scope. The object variable pool is a set of object subpools, each representing the set of variables at each scope of the inheritance chain of the class from which the object was created. Only methods at the same scope can access object variables at any particular scope. This prevents any name conflicts between classes and subclasses, because the object variables for each class are in different scopes.

If you do not change the defaults, only one method of a given scope can run on a single object at a time. Once a method is running on an object, the language processor blocks other methods on other activities from running in the same object at the same scope until the method that is running completes. Thus, if different activities send several messages within a single scope to an object the methods run sequentially.

The next example shows how the default concurrency works.

/* Example of default concurrency for methods of different scopes */

object1 = .subexample~new

say object1~repeat(8, "Object 1 running call 1") /* These calls run */
say object1~repeater(8, "Object 1 running call 2") /* concurrently */
say "Main ended."
exit

::class example
::method repeat
use arg reps,msg
reply "Repeating" msg"," reps "times."
do reps
   say msg
end

::class subexample subclass example
::method repeater
use arg reps,msg
reply "Repeating" msg"," reps "times."
do reps
   say msg
end

The preceding example produces output such as the following:

Repeating Object 1 running call 1, 8 times.
Object 1 running call 1
Repeating Object 1 running call 2, 8 times.
Object 1 running call 1
Object 1 running call 2
Main ended.

Object 1 running call 1
Chapter 12. Concurrency

The following example shows that methods of the same scope do not run concurrently by default.

/* Example of methods with the same scope not running concurrently*/

object1 = .example~new

say object1~repeat(10,"Object 1 running call 1") /* These calls */
say object1~repeat(10,"Object 1 running call 2") /* cannot run */
say "Main ended." /* concurrently. */
exit

::class example
::method repeat
use arg reps,msg
reply "Repeating" msg"," reps "times."
do reps
    say msg
end

The REPEAT method includes a REPLY instruction, but the methods for the two REPEAT messages in the example cannot run concurrently. This is because REPEAT is called twice at the same scope and requires exclusive access to the object variable pool. The REPLY instruction causes the first REPEAT message to transfer its exclusive access to the object variable pool to a new activity and continue execution. The second REPLY message also requires exclusive access and waits until the first method completes.

If the original activity has more than one method active (nested method calls) with exclusive variable access, the first REPLY instruction is unable to transfer its exclusive access to the new activity and must wait until the exclusive access is again available. This may allow another method on the same object to run while the first method waits for exclusive access.

12.3.1. Sending Messages within an Activity

Whenever a message is invoked on an object, the activity acquires exclusive access (a lock) for the object’s scope. Other activities that send messages to the same object that required the locked scope waits until the first activity releases the lock.

Suppose object A is running method Y, which includes:
Sequential processing does not allow method Z to begin until method Y has completed. However, method Y cannot complete until method Z runs. A similar situation occurs when a subclass’s overriding method does some processing and passes a message to its superclasses’ overriding method. Both cases require a special provision: If an invocation running on an activity sends another message to the same object, this method is allowed to run because the activity has already acquired the lock for the scope. This allows nested, nonconcurrent method invocations on a single activity without causing a deadlock situation. The language processor regards these additional messages as subroutine calls.

Here is an example showing the special treatment of single activity messages. The REPEATER and REPEAT methods have the same scope. REPEAT runs on the same object at the same time as the REPEATER method because a message to SELF runs the REPEAT method. The language processor treats this as a subroutine call rather than as concurrently running two methods.

```rexx
/* Example of sending message to SELF */
object1 = .example~new
object2 = .example~new

say object1~repeater(10, "Object 1 running")
say object2~repeater(10, "Object 2 running")

say "Main ended."
exit
::class example
::method repeater
use arg reps,msg
reply "Entered repeater."
say self~repeat(reps,msg)
::method repeat
use arg reps,msg
do reps
   say msg
end
return "Repeated" msg"," reps "times."
```

The activity locking rules also allow indirect object recursion. The following figure illustrates indirect object recursion.
Method M in object A sends object B a message to run method N. Method N sends a message to object A, asking it to run method O. Meanwhile, method M is still running in object A and waiting for a result from method N. A deadlock would result. Because the methods are all running on the same activity, no deadlock occurs.

12.4. Using Additional Concurrency Mechanisms

Rexx has additional concurrency mechanisms that can add full concurrency so that more than one method of a given scope can run in an object at a time:

- The SETUNGUARDED method of the Method class and the UNGUARDED option of the METHOD directive provide unconditional concurrency
- GUARD OFF and GUARD ON control a method’s exclusive access to an object’s scope

12.4.1. SETUNGUARDED Method and UNGUARDED Option

The SETUNGUARDED method of the Method class and the UNGUARDED option of the ::METHOD directive control locking of an object’s scope when a method is invoked. Both let a method run even if another method is active on the same object.

Use the SETUNGUARDED method or UNGUARDED option only for methods that do not need exclusive use of their object variable pool, that is, methods whose execution can interleave with another method’s execution without affecting the object’s integrity. Otherwise, concurrent methods can produce unexpected results.

To use the SETUNGUARDED method for a method you have created with the NEW method of the Method class, you specify:

```
methodname~SETUNGUARDED
```

(See SETUNGUARDED for details about SETUNGUARDED.)

Alternately, you can define a method with the ::METHOD directive, specifying the UNGUARDED option:
Chapter 12. Concurrency

::METHOD methodname UNGUARDED

12.4.2. GUARD ON and GUARD OFF

You might not be able to use the SETUNGUARDED method or UNGUARDED option in all cases. A
method might need exclusive use of its object variables, then allow methods on other activities to run,
and perhaps later need exclusive use again. You can use GUARD ON and GUARD OFF to alternate
between exclusive use of an object’s scope and allowing other activities to use the scope.

By default, a method must wait until a currently running method is finished before it begins. GUARD
OFF lets another method (running on a different activity) that needs exclusive use of the same object
variables become active on the same object. See GUARD for more information.

12.4.3. Guarded Methods

Concurrency requires the activities of concurrently running methods to be synchronized. Critical data
must be safeguarded so diverse methods on other activities do not perform concurrent updates. Guarded
methods satisfy both these needs.

A guarded method combines the UNGUARDED option of the ::METHOD directive or the
SETUNGUARDED method of the Method class with the GUARD instruction.

The UNGUARDED option and the SETUNGUARDED method both provide unconditional concurrency.
Including a GUARD instruction in a method makes concurrency conditional:

GUARD ON WHEN expression

If the expression on the GUARD instruction evaluates to 1 (true), the method continues to run. If the
expression on the GUARD instruction evaluates to 0 (false), the method does not continue running.
GUARD reevaluates the expression whenever the value of an exposed object variable changes. When the
expression evaluates to 1, the method resumes running. You can use GUARD to block running any
method when proceeding is not safe. (See GUARD for details about GUARD.)

Note: It is important to ensure that you use an expression that can be fulfilled. If the condition
expression cannot be met, GUARD ON WHEN puts the program in a continuous wait condition. This
can occur in particular when several activities run concurrently. In this case, a second activity can
make the condition expression invalid before GUARD ON WHEN can use it.

To avoid this, ensure that the GUARD ON WHEN statement is executed before the condition is set to
true. Keep in mind that the sequence of running activities is not determined by the calling sequence, so it
is important to use a logic that is independent of the activity sequence.

12.4.4. Additional Examples

The following example uses REPLY in a method for a write-back cache.
Chapter 12. Concurrency

/* Method Write_Back */
use arg data /* Save data to be written */
reply 0 /* Tell the sender all was OK */
self~disk_write(data) /* Now write the data */

The REPLY instruction returns control to the point at which method Write_Back was called, returning the result 0. The caller of method Write_Back continues processing from this point; meanwhile, method Write_Back also continues processing.

The following example uses a message object. It reads a line asynchronously into the variable nextline:

```
mymsg = infile~start("READLINE") /* Gets message object to carry */
/* message to INFILE */
/* do other work */
nextline=mymsg~result /* Gets result from message object */
```

This creates a message object that waits for the read to finish while the sender continues with other work. When the line is read, the mymsg message object obtains the result and holds it until the sender requests it.

Semaphores and monitors (bounded buffers) synchronize concurrency processes. Giving readers and writers concurrent access is a typical concurrency problem. The following sections show how to use guarded methods to code semaphore and monitor mechanisms and to provide concurrency for readers and writers.

12.4.4.1. Semaphores

A semaphore is a mechanism that controls access to resources, for example, preventing simultaneous access. Synchronization often uses semaphores. Here is an example of a semaphore class:

```
……………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………………

Note: There are functions available that use system semaphores. See SysCreateEventSem, and SysCreateMutexSem.

12.4.4.2. Monitors (Bounded Buffer)

A monitor object consists of a number of client methods, WAIT and SIGNAL methods for client methods to use, and one or more condition variables. Guarded methods provide the functionality of monitors. Do not confuse this with the Monitor class (see The Monitor Class).

::method init
  /* Initialize the bounded buffer */
  expose size in out n
  use arg size
  in = 1
  out = 1
  n = 0
Chapter 12. Concurrency

::method append unguarded
/* Add to the bounded buffer if not full */
expose n size b. in
guard on when n < size
use arg b.in
in = in//size+1
n = n+1

::method take
/* Remove from the bounded buffer if not empty */
expose n b. out size
guard on when n > 0
reply b.out
out = out//size+1
n = n-1

12.4.4.3. Readers and Writers

The concurrency problem of the readers and writers requires that writers exclude writers and readers, whereas readers exclude only writers. The UNGUARDED option is required to allow several concurrent readers.

::method init
expose readers writers
readers = 0
writers = 0

::method read unguarded
/* Read if no one is writing */
expose writers readers
guard on when writers = 0
readers = readers + 1
guard off
/* Read the data */
say "Reading (writers:" writers", readers:" readers")."
guard on
readers = readers - 1

::method write unguarded
/* Write if no-one is writing or reading */
expose writers readers
guard on when writers + readers = 0
writers = writers + 1
/* Write the data */
say "Writing (writers:" writers", readers:" readers")."
writers = writers - 1
Chapter 13. The Security Manager

The security manager provides a special environment that is safe even if agent programs try to perform unexpected actions. The security manager is called if an agent program tries to:

- Call an external function
- Use a host command
- Use the ::REQUIRES directive
- Access the .LOCAL directory
- Access the .ENVIRONMENT directory
- Use a stream name in the input and output built-in functions (CHARIN, CHAROUT, CHARS, LINEIN, LINEOUT, LINES, and STREAM)

13.1. Calls to the Security Manager

When the language processor reaches any of the defined security checkpoints, it sends a message to the security manager for the particular checkpoint. The message has a single argument, a directory of information that pertains to the checkpoint. If the security manager chooses to handle the action instead of the language processor, the security manager uses the checkpoint information directory to pass information back to the language processor.

Security manager methods must return a value of either 0 or 1 to the language processor. A value of 0 indicates that the program is authorized to perform the indicated action. In this case, processing continues as usual. A value of 1 indicates that the security manager performed the action itself. The security manager sets entries in the information directory to pass results for the action back to the language processor. The security manager can also use the RAISE instruction to raise a program error for a prohibited access. Error message 98.948 indicates authorization failures.

The defined checkpoints, with their arguments and return values, are:

CALL

sent for all external function calls. The information directory contains the following entries:

NAME

The name of the invoked function.

ARGUMENTS

An array of the function arguments.

When the CALL method returns 1, indicating that it handled the external call, the security manager places the function result in the information directory as the entry RESULT.
Chapter 13. The Security Manager

COMMAND

sent for all host command instructions. The information directory contains the following entries:

COMMAND

The string that represents the host command.

ADDRESS

The name of the target ADDRESS environment for the command.

When the COMMAND method returns 1, indicating that it handled the command, the security
manager uses the following information directory entries to return the command results:

RC

The command return code. If the entry is not set, a return code of 0 is used.

FAILURE

If a FAILURE entry is added to the information directory, a Rexx FAILURE condition is
raised.

ERROR

If an ERROR entry is added to the information directory, a Rexx ERROR condition is
raised. The ERROR condition is raised only if the FAILURE entry is not set.

REQUIRES

sent whenever a ::REQUIRES directive in the file is processed. The information directory contains
the following entry:

NAME

The name of the file specified on the ::REQUIRES directive.

When the REQUIRES method returns 1, indicating that it handled the request, the entry NAME in
the information directory is replaced with the name of the actual file to load for the request. The
REQUIRES method can also provide a security manager to be used for the program loaded by the
::REQUIRES directive by setting the information direction entry SECURITYMANAGER into the
desired security manager object.

LOCAL

sent whenever Rexx is going to access an entry in the .LOCAL directory as part of the resolution of
the environment symbol name. The information directory contains the following entry:

NAME

The name of the target directory entry.

When the LOCAL method returns 1, indicating that it handled the request, the information directory
entry RESULT contains the directory entry. When RESULT is not set and the method returns 1, this
Chapter 13. The Security Manager

is the same as a failure to find an entry in the .LOCAL directory. Rexx continues with the next step in the name resolution.

ENVIRONMENT

sent whenever Rexx is going to access an entry in the .ENVIRONMENT directory as part of the resolution of the environment symbol name. The information directory contains the following entry:

NAME

The name of the target directory entry.

When the ENVIRONMENT method returns 1, indicating that it handled the request, the information directory entry RESULT contains the directory entry. When RESULT is not set and the method returns 1, this is the same as a failure to find an entry in the .ENVIRONMENT directory.

Rexx continues with the next step in the name resolution.

STREAM

sent whenever one of the Rexx input and output built-in functions (CHARIN, CHAROUT, CHARS, LINEIN, LINEOUT, LINES, or STREAM) needs to resolve a stream name. The information directory contains the following entry:

NAME

The name of the target stream.

When the STREAM method returns 1, the information directory STREAM must be set to an object to be used as the stream target. This should be a stream object or another object that supports the Stream class methods.

METHOD

sent whenever a secure program attempts to send a message for a protected method (see the ::METHOD directive ::METHOD) to an object. The information directory contains the following entries:

OBJECT

The object the protected method is issued against.

NAME

The name of the protected method.

ARGUMENTS

An array containing the method arguments.

When the METHOD method returns 1, indicating that it handled the external call, the function result can be placed in the information directory as the method RESULT.
### 13.1.1. Example

The following agent program includes all the actions for which the security manager defines checkpoints (for example, by calling an external function).

**Figure 13-1. Agent Program**

```rexx
/* Agent */
interpret "echo Hello There"
"dir foo.bar"
call rxfuncadd sysloadfuncs, rexxutil, sysloadfuncs
say result
say syssleep(1)
say linein("c:\profile")
say .array
.object~setmethod("SETMETHOD")
::requires agent2.cmd
```

The following server implements the security manager with three levels of security. For each action the security manager must check (for example, by calling an external routine):

1. The audit manager (Dumper class) writes a record of the event but then permits the action.
2. The closed cell manager (noWay class) does not permit the action to take place and raises an error.
3. The replacement execution environment (Replacer class, a subclass of the noWay class) replaces the prohibited action with a different action.

**Figure 13-2. Example of Server Implementing Security Manager**

```rexx
/* Server implements security manager */
parse arg program
method = .method~newfile(program)
say "Calling program" program "with an audit manager:"
pull
.method~setSecurityManager(.dumper~new(.output))
.go~new~run(method)
say "Calling program" program "with a function replacement execution environment:"
pull
.method~setSecurityManager(.replacer~new)
.go~new~run(method)
say "Calling program" program "with a closed cell manager:"
pull
signal on syntax
.method~setSecurityManager(.noWay~new)
.go~new~run(method)
exit

syntax:
   say "Agent program terminated with an authorization failure"
   exit
::class go subclass object

Chapter 14. Input and Output Streams

Rexx defines Stream class methods to handle input and output and maintains the I/O functions for input and output externals. Using a mixture of Rexx I/O methods and Rexx I/O functions can cause unpredictable results. For example, using the LINEOUT method and the LINEOUT function on the same persistent stream object can cause overlays.

When a Rexx I/O function creates a stream object, the language processor maintains the stream object. When a Rexx I/O method creates a stream object, it is returned to the program to be maintained. Because of this, when Rexx I/O methods and Rexx I/O functions referring to the same stream are in the same program, there are two separate stream objects with different read and write pointers. The program needs to synchronize the read and write pointers of both stream objects, or overlays occur.

To obtain a stream object (for example, MYFIL), you could use:

MyStream = .stream~new("MYFIL")

You can manipulate stream objects with character or line methods:

nextchar = MyStream~charin()
nextline = MyStream~linein()

In addition to stream objects, the language processor defines an external data queue object for interprogram communication. This queue object understands line functions only.

A stream object can have a variety of sources or destinations including files, serial interfaces, displays, or networks. It can be transient or dynamic, for example, data sent or received over a serial interface, or persistent in a static form, for example, a disk file.

Housekeeping for stream objects (opening and closing files, for example) is not explicitly part of the language definition. However, Rexx provides methods, such as CHARIN and LINEIN, that are independent of the operating system and include housekeeping. The COMMAND method provides the stream_command argument for those situations that require more granular access to operating system interfaces.

14.1. The Input and Output Model

The model of input and output for Rexx consists of the following logically distinct parts:

- One or more input stream objects
- One or more output stream objects
- One or more external data queue objects

The Rexx methods, instructions, and built-in routines manipulate these elements as follows.
14.1.1. Input Streams

Input to Rexx programs is in the form of a serial character stream generated by user interaction or has the characteristics of one generated this way. You can add characters to the end of some stream objects asynchronously; other stream objects might be static or synchronous.

The methods and instructions you can use on input stream objects are:

- **CHARIN** method—reads input stream objects as characters.
- **LINEIN** method—reads input stream objects as lines.
- **PARSE PULL** and **PULL** instructions—read the default input stream object (`.INPUT`), if the external data queue is empty. **PULL** is the same as **PARSE UPPER PULL** except that uppercase translation takes place for **PULL**.
- **PARSE LINEIN** instruction—reads lines from the default input stream object regardless of the state of the external data queue. Usually, you can use **PULL** or **PARSE PULL** to read the default input stream object.

In a persistent stream object, the Rexx language processor maintains a current read position. For a persistent stream:

- The **CHARS** method returns the number of characters currently available in an input stream object from the read position through the end of the stream (including any line-end characters).
- The **LINES** method determines if any data remains between the current read position and the end of the input stream object.
- You can move the read position to an arbitrary point in the stream object with:
  - The **SEEK** or **POSITION** method of the Stream class
  - The **COMMAND** method’s **SEEK** or **POSITION** argument
  - The **start** argument of the **CHARIN** method
  - The **line** argument of the **LINEIN** method

  When the stream object is opened, this position is the start of the stream.

In a transient stream, no read position is available. For a transient stream:

- The **CHARS** and **LINES** methods attempt to determine if data is present in the input stream object. These methods return the value 1 for a device if data is waiting to be read or a determination cannot be made. Otherwise, these methods return 0.
- The **SEEK** and **POSITION** methods of the Stream class and the **COMMAND** method’s **SEEK** and **POSITION** arguments are not applicable to transient streams.

14.1.2. Output Streams

Output stream methods provide for output from a Rexx program. Output stream methods are:

- **SAY** instruction—writes to the default output stream object (`.OUTPUT`).
• **CHAROUT** method—writes in character form to either the default or a specified output stream object.

• **LINEOUT** method—writes in lines to either the default or a specified output stream object.

LINEOUT and SAY write the new-line character at the end of each line. Depending on the operating system or hardware, other modifications or formatting can be applied; however, the output data remains a single logical line.

The Rexx language processor maintains the current write position in a stream. It is separate from the current read position. Write positioning is usually at the end of the stream (for example, when the stream object is first opened), so that data can be appended to the end of the stream. For persistent stream objects, you can set the write position to the beginning of the stream to overwrite existing data by giving a value of 1 for the CHAROUT `start` argument or the LINEOUT `line` argument. You can also use the CHAROUT `start` argument, the LINEOUT `line` argument, the SEEK or POSITION method, or the COMMAND method’s SEEK or POSITION `stream_command` to direct sequential output to some arbitrary point in the stream.

**Note:** Once data is in a transient output stream object (for example, a network or serial link), it is no longer accessible to Rexx.

### 14.1.3. External Data Queue

Rexx provides queuing services entirely separate from interprocess communications queues.

The external data queue is a list of character strings that only line operations can access. It is external to Rexx programs in that other Rexx programs can have access to the queue.

The external data queue forms a Rexx-defined channel of communication between programs. Data in the queue is arbitrary; no characters have any special meaning or effect.

Apart from the explicit Rexx operations described here, no detectable change to the queue occurs while a Rexx program is running, except when control leaves the program and is manipulated by external means (such as when an external command or routine is called).

There are two kinds of queues in Rexx. Both kinds are accessed and processed by name.

#### 14.1.3.1. Unnamed Queues

One unnamed queue is automatically provided for each Rexx program in operation. Its name is always "QUEUE:.", and the language processor creates it when Rexx is called and no queue is currently available. All processes that are children of the process that created the queue can access it as long as the process that created it is still running. However, other processes cannot share the same unnamed queue. The queue is deleted when the process that created it ends.

#### 14.1.3.2. Named Queues

Your program creates (and deletes) named queues. You can name the queue yourself or leave the naming to the language processor. Your program must know the name of the queue to use a named queue. To obtain the name of the queue, use the RXQUEUE function:
previous_queue=rxqueue("set",newqueuename)

This sets the new queue name and returns the name of the previous queue.

The following Rexx instructions manipulate the queue:

- **PULL** or **PARSE PULL**--reads a string from the head of the queue. If the queue is empty, these instructions take input from .INPUT.
- **PUSH**--stacks a line on top of the queue (LIFO).
- **QUEUE**--adds a string to the tail of the queue (FIFO).

Rexx functions that manipulate QUEUE: as a device name are:

- **LINEIN("QUEUE:"**)--reads a string from the head of the queue. If the queue is empty the program waits for an entry to be placed on the queue.
- **LINEOUT("QUEUE:","string")**--adds a string to the tail of the queue (FIFO).
- **QUEUED**--returns the number of items remaining in the queue.

Here is an example of using a queue:

**Figure 14-1. Sample Rexx Procedure Using a Queue**

``` Rexx
/* */
/* push/pull WITHOUT multiprogramming support */
/* */
push date() time() /* push date and time */
do 1000 /* let's pass some time */
   nop /* doing nothing */
end /* end of loop */
pull a b /* pull them */
say "Pushed at " a b ", Pulled at " date() time() /* say now and then */

/* */
/* push/pull WITH multiprogramming support */
/* (no error recovery, or unsupported environment tests) */
/* */
newq = RXQUEUE("Create") /* create a unique queue */
oq = RXQUEUE("Set",newq) /* establish new queue */
push date() time() /* push date and time */
do 1000 /* let's spend some time */
   nop /* doing nothing */
end /* end of loop */
pull a b /* get pushed information */
say "Pushed at " a b ", Pulled at " date() time() /* tell user */
call RXQUEUE "Delete",newq /* destroy unique queue created */
call RXQUEUE "Set",oq /* reset to default queue (not required) */
```

Special considerations:

- External programs that must communicate with a Rexx procedure through defined data queues can use the Rexx-provided queue or the queue that QUEUE: references (if the external program runs in a child
process), or they can receive the data queue name through some interprocess communication technique, including argument passing, placement on a prearranged logical queue, or the use of usual interprocess communication mechanisms (for example, pipes, shared memory, or IPC queues).

- Named queues are available across the entire system. Therefore, the names of queues must be unique within the system. If a queue named anyque exists, using the following function:

  ```
  newqueue = RXQUEUE("Create", "ANYQUE")
  ```

  results in an error.

14.1.3.3. Multiprogramming Considerations

The top-level Rexx program in a process tree owns an unnamed queue. However, any child process can modify the queue at any time. No specific process or user owns a named queue. The operations that affect the queue are atomic—the subsystem serializes the resource so that no data integrity problems can occur. However, you are responsible for the synchronization of requests so that two processes accessing the same queue get the data in the order it was placed on the queue.

A specific process owns (creates) an unnamed queue. When that process ends, the language processor deletes the queue. Conversely, the named queues created with `RxQueue("Create", queuename)` exist until you explicitly delete them. The end of a program or procedure that created a named queue does not force the deletion of the private queue. When the process that created a queue ends, any data on the queue remains until the data is read or the queue is deleted. (The function call `RxQueue("Delete", queuename)` deletes a queue.)

If a data queue is deleted by its creator, a procedure, or a program, the items in the queue are also deleted.

14.1.4. Default Stream Names

A stream name can be a file, a queue, a pipe, or any device that supports character-based input and output. If the stream is a file or device, the name can be any valid file specification.

Windows and *nix define three default streams:

- stdin (file descriptor 0) - standard input
- stdout (file descriptor 1) - standard output
- stderr (file descriptor 2) - standard error (output)

Rexx provides `.INPUT` and `.OUTPUT` public objects. They default to the default input and output streams of the operating system. The appropriate default stream object is used when the call to a Rexx I/O function includes no stream name. The following Rexx statements write a line to the default output stream of the operating system:

  ```
  Lineout(,"Hello World")
  .Output~lineout("Hello World")
  ```

Rexx reserves the names STDIN, STDOUT, and STDERR to allow Rexx functions to refer to these stream objects. The checks for these names are not case-sensitive; for example, STDIN, stdin, and sTdIn all refer
Chapter 14. Input and Output Streams

to the standard input stream object. If you need to access a file with one of these names, qualify the name with a directory specification, for example, \stdin.

Rexx also provides access to arbitrary file descriptors that are already open when Rexx is called. The stream name used to access the stream object is HANDLE:x. x is the number of the file descriptor you wish to use. You can use HANDLE:x as any other stream name; it can be the receiver of a Stream class method. If the value of x is not a valid file descriptor, the first I/O operation to that object fails.

Notes:

1. Once you close a HANDLE:x stream object, you cannot reopen it.
2. HANDLE:x is reserved. If you wish to access a file or device with this name, include a directory specification before the name. For example, \HANDLE:x accesses the file HANDLE:x in the current directory.
3. Programs that use the .INPUT and .OUTPUT public objects are independent of the operating environment.

14.1.5. Line versus Character Positioning

Rexx lets you move the read or write position of a persistent stream object to any location within the stream. You can specify this location in terms of characters or lines.

Character positioning is based upon the view of a stream as a simple collection of bytes of data. No special meaning is given to any single character. Character positioning alone can move the stream pointer. For example:

MyStream~charin(10,0)

moves the stream pointer so that the tenth character in MyStream is the next character read. But this does not return any data. If MyStream is opened for reading or writing, any output that was previously written but is still buffered is eliminated. Moving the write position always causes any buffered output to be written.

Line positioning views a stream as a collection of lines of data. There are two ways of positioning by lines. If you open a stream in binary mode and specify a record length of x on the open, a line break occurs every x characters. Line positioning in this case is an extension of character positioning. For example, if you open a stream in binary mode with record length 80, then the following two lines are exactly equivalent.

MyStream~command(position 5 read line)
MyStream~command(position 321 read char)

Remember that streams and other Rexx objects are indexed starting with one rather than zero.

The second way of positioning by lines is for non-binary streams. New-line characters separate lines in non-binary streams. Because the line separator is contained within the stream, ensure accurate line positioning. For example, it is possible to change the line number of the current read position by writing extra new-line characters ahead of the read position or by overwriting existing new-line characters. Thus, line positioning in a non-binary stream object has the following characteristics:
• To do line positioning, it is necessary to read the stream in circumstances such as switching from character methods to line methods or positioning from the end of the stream.

• If you rewrite a stream at a point prior to the read position, the line number of the current read position could become inaccurate.

Note that for both character and line positioning, the index starts with one rather than zero. Thus, character position 1 and line position 1 are equivalent, and both point to the top of the persistent stream object. The Rexx I/O processing uses certain optimizations for positioning. These require that no other process is writing to the stream concurrently and no other program uses or manipulates the same low-level drive, directory specification, and file name that the language processor uses to open the file. If you need to work with a stream in these circumstances, use the system I/O functions.

### 14.2. Implementation

Usually, the dialog between a Rexx program and you as the user takes place on a line-by-line basis and is, therefore, carried out with the SAY, PULL, or PARSE PULL instructions. This technique considerably enhances the usability of many programs, because they can be converted to programmable dialogs by using the external data queue to provide the input you generally type. Use the PARSE LINEIN instruction only when it is necessary to bypass the external data queue.

When a dialog is not on a line-by-line basis, use the serial interfaces the CHARIN and CHAROUT methods provide. These methods are important for input and output in transient stream objects, such as keyboards, printers, or network environments.

Opening and closing of persistent stream objects, such as files, is largely automatic. Generally the first CHARIN, CHAROUT, CHARS, LINEIN, LINEOUT, or LINES message sent to a stream object opens that stream object. It remains open until you explicitly close it with a CHAROUT or LINEOUT or until the program ends. Using the LINEOUT method with only the name of a stream object (and no output string or line) closes the named stream object. The Stream class also provides OPEN and CLOSE methods and the COMMAND method, which can explicitly open or close a stream object.

If you open a stream with the CHARIN, CHAROUT, LINEIN, or LINEOUT methods, it is opened for both reading and writing, if possible. You can use the OPEN method or the COMMAND method to open a stream for read-only or write-only operations.

### 14.3. Operating System Specifics

The COMMAND method of the Stream class determines the state of an input or output stream object and carries out specific operations (see command). It allows Rexx programs to open and close selected stream objects for read-only, write-only, or read and write operations, to move the read and write position within a stream object, to control the locking and buffering characteristics, and to obtain information (such as the size and the date of the last update).
Chapter 14. Input and Output Streams

14.4. Examples of Input and Output

In most circumstances, communication with a user running a Rexx program uses the default input and output stream objects. For a question and answer dialog, the recommended technique is to use the SAY and PULL instructions on the .INPUT and .OUTPUT objects. (You can use PARSE PULL if case-sensitive input is needed.)

It is generally necessary to write to, or read from, stream objects other than the default. For example, the following program copies the contents of one stream to another.

/* FILECOPY.CMD */
/* This routine copies, as lines, the stream or */
/* file that the first argument names to the stream */
/* or file the second argument names. It is assumed */
/* that the name is not an object, as it could be */
/* if it is passed from another Rexx program. */

parse arg inputname, outputname

inputobject = .stream~new(inputname)
outputobject = .stream~new(outputname)

signal on notready

do forever
  outputobject~lineout(inputobject~linein)
end
exit

notready:
  return

As long as lines remain in the named input stream, a line is read and is then immediately written to the named output stream. This program is easy to change so that it filters the lines before writing them.

The following example illustrates how character and line operations can be mixed in a communications program. It converts a character stream into lines.

/* COLLECT.CMD */
/* This routine collects characters from the stream */
/* the first argument names until a line is */
/* complete, and then places the line on the */
/* external data queue. */
/* The second argument is a single character that */
/* identifies the end of a line. */
parse arg inputname, lineendchar

inputobject = .stream~new(inputname)

buffer="" /* zero-length character accumulator */
do forever
  nextchar=inputobject~charin
  if nextchar=lineendchar then leave
  buffer=buffer||nextchar /* add to buffer */
14.5. Errors during Input and Output

The Rexx language offers considerable flexibility in handling errors during input or output. This is provided in the form of a NOTREADY condition that the CALL ON and SIGNAL ON instructions can trap. The STATE and DESCRIPTION methods can elicit further information.

When an error occurs during an input or output operation, the function or method called usually continues without interruption (the output method returns a nonzero count). Depending on the nature of the operation, a program has the option of raising the NOTREADY condition. The NOTREADY condition is similar to the ERROR and FAILURE conditions associated with commands in that it does not cause a terminating error if the condition is raised but is not trapped. After NOTREADY has been raised, the following possibilities exist:

- If the NOTREADY condition is not trapped, processing continues without interruption. The NOTREADY condition remains in the OFF state.
- If SIGNAL ON NOTREADY traps the NOTREADY condition, the NOTREADY condition is raised. Processing of the current clause stops immediately, and the SIGNAL takes place as usual for condition traps.
- If CALL ON NOTREADY traps the NOTREADY condition, the NOTREADY condition is raised, but execution of the current clause is not halted. The NOTREADY condition is put into the delayed state, and processing continues until the end of the current clause. While processing continues, input methods that refer to the same stream can return the null string and output methods can return an appropriate count, depending on the form and timing of the error. At the end of the current clause, the CALL takes place as usual for condition traps.
- If the NOTREADY condition is in the DELAY state (CALL ON NOTREADY traps the NOTREADY condition, which has already been raised), processing continues, and the NOTREADY condition remains in the DELAY state.

After the NOTREADY condition has been raised and is in DELAY state, the “@” option of the CONDITION function returns the stream object being processed when the stream error occurred.

The STATE method of the Stream class returns the stream object state as ERROR, NOTREADY, or UNKNOWN. You can obtain additional information by using the DESCRIPTION method of the Stream class.

**Note:** SAY .OUTPUT and PULL .INPUT never raise the NOTREADY condition. However, the STATE and DESCRIPTION methods can return NOTREADY.
14.6. Summary of Rexx I/O Instructions and Methods

The following lists Rexx I/O instructions and methods:

- CHARIN (see charIn)
- CHAROUT (see charOut)
- CHARS (see chars)
- CLOSE (see close)
- COMMAND (see command)
- DESCRIPTION (see description)
- FLUSH (see flush)
- LINEIN (see lineIn)
- LINEOUT (see lineOut)
- LINES (see lines)
- MAKEARRAY (see makeArray)
- OPEN (see open)
- PARSE LINEIN (see PARSE)
- PARSE PULL (see PARSE)
- POSITION (see position)
- PULL (see PULL)
- PUSH (see PUSH)
- QUALIFY (see qualify)
- QUERY (see query)
- QUEUE (see QUEUE)
- QUEUED (see QUEUED)
- SAY (see SAY)
- SEEK (see seek)
- STATE (see state)
Chapter 15. Debugging Aids

In addition to the TRACE instruction described in TRACE, there are the following debugging aids.

15.1. Interactive Debugging of Programs

The debug facility permits interactively controlled execution of a program. Adding the prefix character ? to the TRACE instruction or the TRACE function (for example, TRACE ?I or TRACE(?I)) turns on interactive debugging and indicates to the user that interactive debugging is active. Further TRACE instructions in the program are ignored, and the language processor pauses after nearly all instructions that are traced at the console (see Debugging Aids for the exceptions). When the language processor pauses, the following debug actions are available:

- Entering a null line causes the language processor to continue with the execution until the next pause for debugging input. Repeatedly entering a null line, therefore, steps from pause point to pause point. For TRACE ?A, for example, this is equivalent to single-stepping through the program.
- Entering an equal sign (=) with no surrounding whitespace causes the language processor to reexecute the clause last traced. For example, if an IF clause is about to take the wrong branch, you can change the value of the variables on which it depends, and then reexecute it.
  Once the clause has been reexecuted, the language processor pauses again.
- Anything else entered is treated as a line of one or more clauses, and processed immediately (that is, as though DO; line; END; had been inserted in the program). The same rules apply as for the INTERPRET instruction (for example, DO-END constructs must be complete). If an instruction contains a syntax error, a standard message is displayed and you are prompted for input again. Similarly, all other SIGNAL conditions are disabled while the string is processed to prevent unintentional transfer of control.
  During interpretation of the string, no tracing takes place, except that nonzero return codes from commands are displayed. The special variable RC and the environment symbol .RS are not set by commands executed from the string. Once the string has been processed, the language processor pauses again for further debugging input.

Interactive debug is turned off in either of the following cases:

- A TRACE instruction uses the ? prefix while interactive debug is in effect
- At any time, if TRACE 0 or TRACE with no options is entered

15.2. Debugging Aids

The numeric form of the TRACE instruction can be used to allow sections of the program to be executed without pause for debugging input. TRACE n (that is, a positive result) allows execution to continue, skipping the next n pauses (when interactive debugging is or becomes active). TRACE ~n (that is, a negative result) allows execution to continue without pause and with tracing inhibited for n clauses that would otherwise be traced. The trace action a TRACE instruction selects is saved and restored across
subroutine calls. This means that if you are stepping through a program (for example, after using TRACE ?R to trace results) and then enter a subroutine in which you have no interest, you can enter TRACE 0 to turn off tracing. No further instructions in the subroutine are traced, but on return to the caller, tracing is restored.

Similarly, if you are interested only in a subroutine, you can put a TRACE ?R instruction at its start. Having traced the routine, the original status of tracing is restored and, if tracing was off on entry to the subroutine, tracing and interactive debugging are turned off until the next entry to the subroutine.

Because any instructions can be executed in interactive debugging you have considerable control over the execution.

The following are some examples:

```rxml
Say expr  /* displays the result of evaluating the */
       /* expression */
name=expr  /* alters the value of a variable */
Trace O  /* (or Trace with no options) turns off */
       /* interactive debugging and all tracing */
Trace ?A  /* turns off interactive debugging but */
       /* continues tracing all clauses */
exit     /* terminates execution of the program */

do i=1 to 10; say stem.i; end
       /* displays ten elements of the array stem. */
```

Exceptions: Some clauses cannot safely be reexecuted, and therefore the language processor does not pause after them, even if they are traced. These are:

- Any repetitive DO clause, on the second or subsequent time around the loop.
- All END clauses.
- All THEN, ELSE, OTHERWISE, or null clauses.
- All RETURN and EXIT clauses.
- All SIGNAL clauses (but the language processor pauses after the target label is traced).
- Any clause that causes a syntax error. They can be trapped by SIGNAL ON SYNTAX, but cannot be reexecuted.

A pause occurs after a REPLY instruction, but the REPLY instruction cannot be reexecuted.

### 15.3. RXTRACE Variable

When the interpreter starts the interpretation of a Rexx procedure it checks the setting of the special environment variable, RXTRACE. If RXTRACE has been set to ON (not case-sensitive), the interpreter starts in interactive debug mode as if the Rexx instruction TRACE '?'R had been the first interpretable
instruction. All other settings of `RXTRACE` are ignored. `RXTRACE` is only checked when starting a new Rexx procedure.

Use the SET command to set or query an environment variable or query all environment variables. To delete an environment variable, use SET `variable=`.
Chapter 16. Reserved Keywords

Keywords can be used as ordinary symbols in many unambiguous situations. The precise rules are given in this chapter.

The free syntax of Rexx implies that some symbols are reserved for use by the language processor in certain contexts.

Within particular instructions, some symbols can be reserved to separate the parts of the instruction. These symbols are referred to as keywords. Examples of Rexx keywords are the WHILE keyword in a DO instruction and the THEN keyword, which acts as a clause terminator in this case, following an IF or WHEN clause.

Apart from these cases, only simple symbols that are the first token in a clause and that are not followed by an "=" or ":" are checked to see if they are instruction keywords. The symbols can be freely used elsewhere in clauses without being understood as keywords.

Be careful with host commands or subcommands with the same name as Rexx keywords. To avoid problems, enclose at least the command or subcommand in quotation marks. For example:

"DELETE" Fn"."Ext

You can then also use the SIGNAL ON NOVALUE condition to check the integrity of an executable. Alternatively, you can precede such command strings with two adjacent quotation marks to concatenate the null string to the beginning. For example:

""Erase Fn"."Ext

A third option is to enclose the entire expression, or the first symbol, in parentheses. For example:

(Erase Fn"."Ext)
Chapter 17. Special Variables

A special variable can be set automatically during processing of a Rexx program. There are five special variables:

**RC**

is set to the return code from any executed command (including those submitted with the ADDRESS instruction). After the trapping of ERROR or FAILURE conditions, it is also set to the command return code. When the SYNTAX condition is trapped, RC is set to the syntax error number (1-99). RC is unchanged when any other condition is trapped.

*Note:* Commands executed manually during interactive tracing do not change the value of RC.

**RESULT**

is set by a RETURN instruction in a subroutine that has been called, or a method that was activated by a message instruction, if the RETURN instruction specifies an expression. (See EXIT, REPLY, and RETURN.) If the RETURN instruction has no expression, RESULT is dropped (becomes uninitialized). Note that an EXIT or REPLY instruction also sets RESULT.

**SELF**

is set when a method is activated. Its value is the object that forms the execution context for the method (that is, the receiver object of the activating message). You can use SELF to:

- Run a method in an object in which a method is already running. For example, a Find_Clues method is running in an object called Mystery_Novel. When Find_Clues finds a clue, it sends a Read_Last_Page message to Mystery_Novel:

  ```
  self~Read_Last_Page
  ```

- Pass references about an object to the methods of other objects. For example, a Sing method is running in object Song. The code Singer2~Duet(self) would give the Duet method access to the same Song.

**SIGL**

is set to the line number of the last instruction that caused a transfer of control to a label (that is, any SIGNAL, CALL, internal function call, or trapped condition). See The Special Variable SIGL.

**SUPER**

is set when a method is activated. Its value is the class object that is the usual starting point for a superclass method lookup for the SELF object. This is the first immediate superclass of the class that defined the method currently running. (See Classes and Instances.) If the current method was defined by a class in the direct inheritance chain, SUPER will always refer to the immediate superclass that class. If the current method is defined by a mixin class, the SUPER variable will always be the superperclass of the mixin class.
Chapter 17. Special Variables

The special variable SUPER lets you call a method in the superclass of an object. For example, the following Savings class has INIT methods that the Savings class, Account class, and Object class define.

::class Account

::method INIT
  expose balance
  use arg balance
  self~init:super /* Forwards to the Object INIT method */

::method TYPE
  return "an account"

::method name attribute

::class Savings subclass Account

::method INIT
  expose interest_rate
  use arg balance, interest_rate
  self~init:super(balance) /* Forwards to the Account INIT method */

::method type
  return "a savings account"

When the INIT method of the Savings class is called, the variable SUPER is set to the Account class object. The instruction:

self~init:super(balance) /* Forwards to the Account INIT method */

calls the INIT method of the Account class rather than recursively calling the INIT method of the Savings class. When the INIT method of the Account class is called, the variable SUPER is assigned to the Object class.

self~init:super /* Forwards to the Object INIT method */

calls the INIT method that the Object class defines.

You can alter these variables like any other variable, but the language processor continues to set RC, RESULT, and SIGL automatically when appropriate. The EXPOSE, PROCEDURE, USE and DROP instructions also affect these variables.

Rexx also supplies functions that indirectly affect the execution of a program. An example is the name that the program was called by and the source of the program (which are available using the PARSE SOURCE instruction). In addition, PARSE VERSION makes available the language version and date of Rexx implementation that is running. The built-in functions ADDRESS, DIGITS, FUZZ, FORM, and TRACE return other settings that affect the execution of a program.
Chapter 18. Useful Services

The following section describes useful commands and services.

18.1. Windows Commands

COPY
  copies files.

DELETE
  deletes files.

DIR
  displays disk directories.

ERASE
  erases files.

MODE
  controls input and output device characteristics.

PATH
  defines or displays the search path for commands and Rexx programs. See also Search Order.

SET
  displays or changes Windows environment variables. See also VALUE.

18.2. Linux Commands

Most Commonly used commands are:

cp
  copies files and directories.

mv
  moves files and directories.

rm
  removes files and directories.
Chapter 18. Useful Services

is

displays files and directories.

echo $path

defines or displays the search path for commands and Rexx programs. See also Search Order.

e

displays or changes Linux environment variables.

Any other Linux command can be used. For a description of these commands, see the respective Linux documentation (for example, man-pages).

18.3. Subcommand Handler Services

For a complete subcommand handler description, see the Open Object Rexx: Programming Guide.

18.3.1. The RXSUBCOM Command

The RXSUBCOM command registers, drops, and queries Rexx subcommand handlers. A Rexx procedure or script file can use RXSUBCOM to register dynamic-link library subcommand handlers. Once the subcommand handler is registered, a Rexx program can send commands to the subcommand handler with the Rexx ADDRESS instruction. For example, Rexx Dialog Manager programs use RXSUBCOM to register the ISPCIR subcommand handler.

"RXSUBCOM REGISTER ISPCIR ISPCIR ISPCIR"
Address ispcir

See ADDRESS for details of the ADDRESS instruction.

18.3.1.1. RXSUBCOM REGISTER

RXSUBCOM REGISTER registers a dynamic-link library subcommand handler. This command makes a command environment available to Rexx.

>~RXSUBCOM--REGISTER--envname--dllname--procname-------------><

Parameters:

envname

The subcommand handler name. The Rexx ADDRESS instruction uses envname to send commands to the subcommand handler.

dllname

The name of the dynamic-link library file containing the subcommand handler routine.
**Chapter 18. Useful Services**

**procname**

The name of the dynamic-link library procedure within `dllname` that Rexx calls as a subcommand handler.

Return codes:

0

The command environment has been registered.

10

A duplicate registration has occurred. An `envname` subcommand handler in a different dynamic-link library has already been registered. Both the new subcommand handler and the existing subcommand handler can be used.

30

The registration has failed. Subcommand handler `envname` in library `dllname` is already registered.

1002

RXSUBCOM was unable to obtain the memory necessary to register the subcommand handler.

-1

A parameter is missing or incorrectly specified.

**18.3.1.2. RXSUBCOM DROP**

RXSUBCOM DROP deregisters a subcommand handler.

```bash
>>-RXSUBCOM--DROP--envname--+-dllname--+
```

**Parameters:**

`envname`

The name of the subcommand handler.

`dllname`

The name of the dynamic-link file containing the subcommand handler routine.

Return codes:

0

The subcommand handler was successfully deregistered.

30

The subcommand handler does not exist.
Chapter 18. Useful Services

40
The environment was registered by a different process as RXSUBCOM_NONDROP.

-1
A parameter is missing or specified incorrectly.

18.3.1.3. RXSUBCOM QUERY
RXSUBCOM QUERY checks the existence of a subcommand handler. The query result is returned.

```bash
>>-RXSUBCOM--QUERY--envname--dllname->
```

**Parameters:**

- `envname`
  The name of the subcommand handler.

- `dllname`
  The name of the dynamic-link file containing the subcommand handler routine.

**Return codes:**

- 0
  The subcommand handler is registered.

- 30
  The subcommand handler is not registered.

- -1
  A parameter is missing or specified incorrectly.

18.3.1.4. RXSUBCOM LOAD
RXSUBCOM LOAD loads a subcommand handler dynamic-link library.

```bash
>>-RXSUBCOM--LOAD--envname--dllname->
```

**Parameters:**

- `envname`
  The name of the subcommand handler.
libname

The name of the dynamic-link file containing the subcommand handler routine.

**Return codes:**

0

The dynamic-link library was located and loaded successfully.

50

The dynamic-link library was not located or could not be loaded.

-1

A parameter is missing or incorrectly specified.

### 18.3.2. The RXQUEUE Filter

RXQUEUE uses the environment variable RXQUEUE for the default queue name. When RXQUEUE does not have a value, RXQUEUE uses SESSION for the queue name.

For a full description of Rexx queue services for applications programming, see External Data Queue.

**Parameters:**

- `queue name/LIFO`
  
  stacks items from STDIN last in, first out (LIFO) on a Rexx queue.

- `queue name/FIFO`
  
  queues items from STDIN first in, first out (FIFO) on a Rexx queue.

- `queue name/CLEAR`

  removes all lines from a Rexx queue.

RXQUEUE takes output lines from another program and places them on a Rexx queue. A Rexx procedure can use RXQUEUE to capture operating system command and program output for processing. RXQUEUE can direct output to any Rexx queue, either FIFO (first in, first out) or LIFO (last in, first out).

RXQUEUE uses the environment variable RXQUEUE for the default queue name. When RXQUEUE does not have a value, RXQUEUE uses SESSION for the queue name.

The following example obtains the Windows version number with RXQUEUE:

```*/ Sample program to show simple use of RXQUEUE */```

Chapter 18. Useful Services

/* Find out the Windows version number, using the VER command. VER produces two lines of output; one blank line, and one line with the format "The Windows Version is n.nn" */

"VER |RXQUEUE" /* Put the data on the Queue */ pull . /* Get and discard the blank line */ Pull . "VERSION" number "]" /* The bracket is required for Windows 95, not for Windows NT */ Say "We are running on Windows Version" number

Note that the syntax of the version string that is returned by Windows can vary, so the parsing syntax for retrieving the version number may be different.

The following example processes output from the DIR command:

/* Sample program to show how to use the RXQUEUE filter */ /* This program filters the output from a DIR command, */ /* ignoring small files. It displays a list of the */ /* large files, and the total of the sizes of the large */ /* files. */

size_limit = 10000 /* The dividing line */ /* between large and small*/ size_total = 0 /* Sum of large file sizes*/ NUMERIC DIGITS 12 /* Set up to handle very */ /* large numbers */ /* Create a new queue so that this program cannot */ /* interfere with data placed on the queue by another */ /* program. */

queue_name = rxqueue("Create") Call rxqueue "Set", queue_name

"DIR /N | RXQUEUE" queue_name

/* DIR output starts with five header lines */ /* DIR output starts with five header lines */ Do 5 Pull . /* discard header line */ End

/* Now all the lines are file or directory lines, */ /* except for one at the end. */ /* Now all the lines are file or directory lines, */ Do queued() - 1 /* loop for lines we want */ /* loop for lines we want */ Parse Pull . size . name ./* get one name and size */ /* get one name and size */ /* If the size field says ">DIR">, we ignore this */ /* line. */ /* If the size field says ">DIR">, we ignore this */ If size <> "<DIR>" Then /* If size <> "<DIR>" Then */ /* Now check size, and display */ /* Now check size, and display */ If size > size_limit Then Do /* If size > size_limit Then Do */ Say format(size,12) name /* Say format(size,12) name */ size_total = size_total + size /* size_total = size_total + size */

580 ooRexx Reference Version 4.0.0
Chapter 18. Useful Services

End

Say "The total size of those files is" size_total

/* Now we are done with the queue. We delete it, which */
/* discards the line remaining in it. */

Call rxqueue "DELETE", queue_name

18.4. Distributing Programs without Source

Open Object Rexx comes with a utility called RexxC. You can use this utility to produce versions of your programs that do not include the original program source. You can use these programs to replace any Rexx program file that includes the source, with the following restrictions:

1. The SOURCELINE built-in function returns 0 for the number of lines in the program and raises an error for all attempts to retrieve a line.

2. A sourceless program may not be traced. The TRACE instruction runs without error, but no tracing of instruction lines, expression results, or intermediate expression values occurs.

The syntax of the RexxC utility is:

```
>>-RexxC--inputfile--+------------+--+----+--------------------><
+------outputfile-+ +-/s-+
```

If you specify the `outputfile`, the language processor processes the `inputfile` and writes the executable version of the program to the `outputfile`. If the `outputfile` already exists, it is replaced.

If the language processor detects a syntax error while processing the program, it reports the error and stops processing without creating a new output file. If you omit the `outputfile`, the language processor performs a syntax check on the program without writing the executable version to a file.

You can use the `/s` option to suppress the display of the information about the interpreter used.

**Note:** You can use the in-storage capabilities of the RexxStart programming interface to process the file image of the output file.

With version 2.1, the tokenized form has changed. All Open Object Rexx editions contain a utility called RxMigrate that can be used to change old tokenized forms to the new one. The recommended procedure is to create a new tokenized file from the original source with the new version of Open Object Rexx. However, if the source code is no longer available, RxMigrate can be used to convert the old tokenized file. The syntax of the RxMigrate utility is:

```
>>-RxMigrate--inputfile--outputfile----------------------------><
```
Chapter 18. Useful Services
Appendix A. Using DO and LOOP

This appendix provides you with additional information about the DO and LOOP keyword instructions.

A.1. Simple DO Group

If you specify neither repetitor nor conditional, the DO construct only groups a number of instructions together. They are processed once. For example:

/* The two instructions between DO and END are both */
/* processed if A has the value "3". */
If a=3 then Do
a=a+2
Say "Smile!"
End

A.2. Repetitive Loops

If a DO or LOOP instruction has a repetitor phrase, a conditional phrase, or both, the group of instructions forms a repetitive loop. The instructions are processed according to the repetitor phrase, optionally modified by the conditional phrase. (See Conditional Phrases (WHILE and UNTIL).)

A.2.1. Simple Repetitive Loops

A simple repetitive loop is a repetitive loop in which the repetitor phrase is an expression that evaluates to a count of the iterations.

If repetitor is omitted but there is a conditional or if the repetitor is FOREVER, the group of instructions is processed until the condition is satisfied or a Rexx instruction ends the loop (for example, LEAVE).

In the simple form of a repetitive loop, expr is evaluated immediately (and must result in a positive whole number or zero), and the loop is then processed that many times.

Example:

/* This displays "Hello" five times */
Loop 5
say "Hello"
end

Note that, similar to the distinction between a command and an assignment, if the first token of expr is a symbol and the second token is (or starts with) =, the controlled form of repetitor is expected.
A.2.2. Controlled Repetitive Loops

The controlled form specifies control1, a control variable that is assigned an initial value (the result of expr1, formatted as though 0 had been added) before the first execution of the instruction list. The variable is then stepped by adding the result of exprb before the second and subsequent times that the instruction list is processed.

The instruction list is processed repeatedly as long as the end condition (determined by the result of exprt) is not met. If exprb is positive or 0, the loop is ended when control1 is greater than exprt. If negative, the loop is ended when control1 is less than exprt.

The expr1, exprt, and exprb options must result in numbers. They are evaluated only once, before the loop begins and before the control variable is set to its initial value. The default value for exprb is 1. If exprt is omitted, the loop runs infinitely unless some other condition stops it.

Example:

```
Loop I=3 to -2 by -1 /* Displays: */
say i /* 3 */
end /* 2 */
/* 1 */
/* 0 */
/* -1 */
/* -2 */
```

The numbers do not have to be whole numbers:

Example:

```
I=0.3 /* Displays: */
Do Y=I to I+4 by 0.7 /* 0.3 */
say Y /* 1.0 */
end /* 1.7 */
/* 2.4 */
/* 3.1 */
/* 3.8 */
```

The control variable can be altered within the loop, and this can affect the iteration of the loop. Altering the value of the control variable is not considered good programming practice, though it can be appropriate in certain circumstances.

Note that the end condition is tested at the start of each iteration (and after the control variable is stepped, on the second and subsequent iterations). Therefore, if the end condition is met immediately, the group of instructions can be skipped entirely. Note also that the control variable is referred to by name. If, for example, the compound name A.I is used for the control variable, altering I within the loop causes a change in the control variable.

The execution of a controlled loop can be limited further by a FOR phrase. In this case, you must specify exprf, and it must evaluate to a positive whole number or zero. This acts like the repetition count in a simple repetitive loop, and sets a limit to the number of iterations around the loop if no other condition stops it. Like the TO and BY expressions, it is evaluated only once--when the instruction is first processed and before the control variable receives its initial value. Like the TO condition, the FOR condition is checked at the start of each iteration.

Example:
Appendix A. Using DO and LOOP

Loop Y=0.3 to 4.3 by 0.7 for 3 /* Displays: */
say Y /* 0.3 */
end /* 1.0 */ /* 1.7 */

In a controlled loop, the control1 name describing the control variable can be specified on the END clause. This name must match control1 in the DO or LOOP clause in all respects except the case (note that no substitution for compound variables is carried out). Otherwise, a syntax error results. This enables the nesting of loops to be checked automatically, with minimal overhead.

Example:

Loop K=1 to 10
...
...
End k /* Checks that this is the END for K loop */

Note: The NUMERIC settings can affect the successive values of the control variable because Rexx arithmetic rules apply to the computation of stepping the control variable.

A.3. Repetitive Loops over Collections

A collection loop specifies a control variable, control2, which receives a different value on each repetition of the loop. (For more information on control2, see DO.) These different values are taken from successive values of collection. The collection is any expression that evaluates to an object that provides a MAKEARRAY method, including stem variables. The collection returned determines the set of values and their order. Array, List, and Queue items return an array with the items in the appropriate order, as do Streams. Tables, Stems, Directories, etc. are not ordered so the items get placed in the array in no particular order.

If the collection is a stem variable, the values are the tail names that have been explicitly assigned to the given stem. The order of the tail names is unspecified, and a program should not rely on any order.

For other collection objects, the MAKEARRAY method of the specific collection class determines the values assigned to the control variable.

All values for the loop iteration are obtained at the beginning of the loop. Therefore, changes to the target collection object do not affect the loop iteration. For example, using DROP to change the set of tails associated with a stem or using a new value as a tail does not change the number of loop iterations or the values over which the loop iterates.

As with controlled repetition, you can specify the symbol that describes the control variable on the END clause. The control variable is referenced by name, and you can change it within the loop (although this would not usually be useful). You can also specify the control variable name on an ITERATE or LEAVE instruction.

Example:
Appendix A. Using DO and LOOP

```
Astem.=0
Astem.3="CCC"
Astem.24="XXX"
loop k over Astem.
   say k Astem.k
end k
```

This example can produce:

```
3  CCC
24 XXX

or:
24 XXX
3  CCC
```

See Concept of a Loop for a diagram.

A.4. Conditional Phrases (WHILE and UNTIL)

A conditional phrase can modify the iteration of a repetitive loop. It can cause the termination of a loop. It can follow any of the forms of repetitor (none, FOREVER, simple, or controlled). If you specify WHILE or UNTIL, `exprw` or `expru`, respectively, is evaluated after each loop using the latest values of all variables, and the loop is ended if `exprw` evaluates to 0 or `expru` evaluates to 1.

For a WHILE loop, the condition is evaluated at the top of the group of instructions. For an UNTIL loop, the condition is evaluated at the bottom--before the control variable has been stepped.

Example:

```
Loop I=1 to 10 by 2 until i>6
   say i
end
/* Displays: "1" "3" "5" "7" */
```

Note: Using the LEAVE or ITERATE instructions can also modify the execution of repetitive loops.

A.5. LABEL Phrase

The LABEL phrase may be used to specify a name for the DO or LOOP. The can optionally be used for

- a LEAVE instruction to identify the block to be left
- an ITERATE instruction to identify the loop to be iterated
- the END clause of the block, for additional checking.
Example:

Loop label outer I=1 to 10 by 2
  ...
  if i > 5 then do label inner
  ...
  if a = b then leave inner
  ...
  if c = b then iterate outer
  end inner
  ...
  say i
end outer
/* Displays: "1" "3" "5" "7" */

In this example, the LEAVE instruction will exit the inner DO block. The ITERATE instruction will iterate the out LOOP instruction.

If a LABEL phrase is used on a DO or LOOP, it overrides any name derived from any control variable name. That is, if label is used, the control variable cannot be used on a LEAVE, ITERATE, or END instruction to identify the block. Only the label name is valid.
Appendix A. Using DO and LOOP

A.6. Conceptual Model of Loops

Figure A-1. Concept of a Loop

Evaluate expr+0 or expri+1 and then exprt+0, exprb+0, and exprf+0 in order written.

Assign start value to control variable.

Use TO value (exprt) to test control variable for termination.

Use count of iterations (exprr) to test for termination.

Use FOR value (exprf) to test for termination.

Use WHILE expression (exprw) to test for termination.

Process instructions in the DO/LOOP group.

Use UNTIL expression (expri) to test for termination.

Use BY value (exprb) to update control variable.

Discontinue processing of DO/LOOP group if TO value is exceeded.

Discontinue processing of DO/LOOP group if number of iterations is exceeded.

Discontinue processing of DO/LOOP group if FOR value (number of iterations through the loop) is exceeded.

Discontinue processing of DO/LOOP group if WHILE condition is not met.

Discontinue processing of DO/LOOP group if UNTIL condition is met.
Appendix A. Using DO and LOOP

Figure A-2. Concept of Repetitive Loop over Collection

1. Evaluate array = (collection)~makeArray
2. Index = 1
3. Test index > array~items
   - If yes: Stop processing
   - If no: Proceed
4. Control variable = array[index]
5. (WHILE expression)
6. Process instruction(s)
7. (UNTIL expression)
8. Index = index + 1
Appendix B. Migration

This appendix lists some differences between Object Rexx and earlier versions of Rexx, and between Object Rexx for OS/2 and Open Object Rexx for Windows NT and *nix environments.

B.1. Error Codes and Return Codes

Some error codes have changed and some have been added. Also, for most errors you now receive two error messages. The first should be similar or identical to the message you would have seen previously. The second provides additional and more detailed information. So, for example, where you formerly received "Invalid Call to Routine", you now get further information on what is wrong with the call. Also, the return codes of host commands might be different.

B.2. Error Detection and Reporting

Some errors are now detected earlier. Formerly, Rexx would wait until it encountered an error during execution to report it to you. Now, some errors are reported before the first instruction in your Rexx script is executed. In particular, syntax errors are reported after you have invoked the program, but before it starts execution.

B.3. Environment Variables

Environment variables set within an Object Rexx program by the VALUE function or "SET" are not kept after the program termination.

B.4. Stems versus Collections

Stems are a general data structure that are powerful but abstract. In earlier releases of Rexx, you could use stems to create data structures of all types, such as arrays, stacks, and queues. These data structures were semantically neutral. Because stems were the basis for all of them, the code itself gave no hint of which structure was implemented and for what purpose.

The best data structure job is not always the most powerful and abstract but the most specific and restrictive. Object Rexx provides a variety of data structures in the collection classes. This helps reduce errors because you can select the data structure that best meets your requirements. It also helps eliminate the misuse of data structures and adds a semantic context that makes programs easier to maintain.
Appendix B. Migration

B.5. Input and Output Using Functions and Methods

Do not use a mixture of methods and functions for input and output because it can cause unpredictable results. For example, using the LINEOUT method and the LINEOUT function on the same persistent stream object can cause overlays.

When a Rexx I/O function creates a stream object, the language processor stores the reference to the stream object in an internal table. When an I/O method creates a stream object, it is returned to the program to be maintained. Therefore, these two stream objects are separate stream objects with different read and write pointers. The program needs to synchronize the read and write pointers of both stream objects. Otherwise, overlays would occur.

B.6. .Environment

The .Environment directory is local and not system-global as in OS/2. This means that there is no difference between the scope of the .Local and .Environment directories.

B.7. Deleting Environment Variables

Value(envvar,"","ENVIRONMENT") does not delete an environment variable but sets the environment variable’s value to "". Use Value(envvar,nil,"ENVIRONMENT") to delete an environment variable.

B.8. Trace in Macrospace

Functions in macrospace cannot be traced using the TRACE keyword. These functions are stored in an optimized format without source code. If you want to trace functions, do not load them into macrospace.
Appendix C. Error Numbers and Messages

The error numbers produced by syntax errors during the processing of Rexx programs are all in the range 1 to 99. Errors are raised in response to conditions, for example, SYNTAX, NOMETHOD, and PROPAGATE. When the condition is SYNTAX, the value of the error number is placed in the variable RC when SIGNAL ON SYNTAX is trapped.

You can use the ERRORTEXT built-in function to return the text of an error message.

Some errors have associated subcodes. A subcode is a one- to three-digit decimal extension to the error number, for example, 115 in 40.115. When an error subcode is available, additional information that further defines the source of the error is given. The ERRORTEXT built-in function cannot retrieve the secondary message, but it is available from the condition object created when SIGNAL ON SYNTAX traps an error.

C.1. Error List

C.1.1. Error 3 - Failure during initialization

Explanation:
The REXX program could not be read from the disk.
The associated subcodes are:

001

Failure during initialization: File "filename" is unreadable

900

message

901

Failure during initialization: Program "program" was not found

902

Error writing output file "file"

903

Program "program_name" cannot be run by this version of the REXX interpreter

904

Failure during initialization: Program "program" needs to be tokenized. To run untokenized scripts you need a full version of Object REXX.
Appendix C. Error Numbers and Messages

C.1.2. Error 4 - Program interrupted
Explanation:
The system interrupted the execution of your program because of an error or a user request.
The associated subcodes are:

001
   Program interrupted with condition condition
900
   message

C.1.3. Error 5 - System resources exhausted
Explanation:
While trying to execute a program, the language processor was unable to get the resources it needed to continue. For example, it could not get the space needed for its work areas or variables. The program that called the language processor might itself have already used up most of the available storage. Or a request for storage might have been for more than the implementation maximum.
The associated subcodes are:

900
   message

C.1.4. Error 6 - Unmatched "/**" or quote
Explanation:
A comment or literal string was started but never finished. This could be because the language processor detected:

• The end of the program (or the end of the string in an INTERPRET instruction) without finding the ending "/**" for a comment or the ending quotation mark for a literal string
• The end of the line for a literal string.

The associated subcodes are:

001
   Unmatched comment delimiter ("/**") on line line_number
002
   Unmatched single quote (‘)
Appendix C. Error Numbers and Messages

003
Unmatched double quote ("")

900
message

C.1.5. Error 7 - WHEN or OTHERWISE expected

Explanation:
At least one WHEN construct (and possibly an OTHERWISE clause) is expected within a SELECT instruction. This message is issued if any other instruction is found or there is no WHEN construct before the OTHERWISE or all WHEN expressions are false and an OTHERWISE is not present. A common cause of this error is if you forget the DO and END around the list of instructions following a WHEN. For example:

WRONG

Select
When a=c then
Say 'A equals C'
exit
Otherwise nop
end

RIGHT

Select
When a=c then DO
Say 'A equals C'
exit
Otherwise nop
end

The associated subcodes are:

001
SELECT on line line_number requires WHEN

002
SELECT on line line_number requires WHEN, OTHERWISE, or END

003
All WHEN expressions of SELECT are false; OTHERWISE expected

C.1.6. Error 8 - Unexpected THEN or ELSE

Explanation:
A THEN or an ELSE clause was found that does not match a corresponding IF or WHEN clause. This often occurs because of a missing END or DO...END in the THEN part of a complex IF...THEN...ELSE construction. For example:

WRONG

If a=c then do;

RIGHT

If a=c then do;
Appendix C. Error Numbers and Messages

Say EQUALS Say EQUALS
exit exit
else end
Say NOT EQUALS else
Say NOT EQUALS

The associated subcodes are:

001
THEN has no corresponding IF or WHEN clause

002
ELSE has no corresponding THEN clause

C.1.7. Error 9 - Unexpected WHEN or OTHERWISE

Explanation:
A WHEN or OTHERWISE was found outside of a SELECT construction. You might have accidentally
enclosed the instruction in a DO...END construction by leaving out an END, or you might have tried to
branch to it with a SIGNAL instruction (which does not work because the SELECT is then ended).
The associated subcodes are:

001
WHEN has no corresponding SELECT

002
OTHERWISE has no corresponding SELECT

C.1.8. Error 10 - Unexpected or unmatched END

Explanation:
More ENDS were found in your program than DO or SELECT instructions, or the ENDS did not match
the DO or SELECT instructions. This message also occurs if you try to transfer control into the middle
of a loop using SIGNAL. In this case, the language processor does not expect the END because it did not
process the previous DO instruction. Remember also that SIGNAL deactivates any current loops, so it
cannot transfer control from one place inside a loop to another.

Another cause for this message is placing an END immediately after a THEN or ELSE subkeyword or
specifying a name on the END keyword that does not match the name following DO. Putting the name of
the control variable on ENDS that close repetitive loops can also help locate this kind of error.
The associated subcodes are:

001
END has no corresponding DO or SELECT
Appendix C. Error Numbers and Messages

002
Symbol following END ("symbol") must match block specification name ("control_variable") on line line_number or be omitted

003
END corresponding to block on line symbol must not have a symbol following it because there is no LABEL or control variable; found "line_number"

004
Symbol following END ("symbol") must match LABEL of SELECT specification ("control_variable") on line line_number or be omitted

005
END must not immediately follow THEN

006
END must not immediately follow ELSE

007
END corresponding to SELECT on line symbol must not have a symbol following it because there is no LABEL; found "line_number"

C.1.9. Error 11 - Control stack full

Explanation:
Your program exceeds the nesting level limit for control structures (for example, DO..END and IF..THEN..ELSE). This could be because of a looping INTERPRET instruction, such as:

```plaintext
line='INTERPRET line'
INTERPRET line
```

These lines loop until they exceed the nesting level limit and the language processor issues this message. Similarly, a recursive subroutine or internal function that does not end correctly can loop until it causes this message.

The associated subcodes are:

001
Insufficient control stack space; cannot continue execution

900
message
Appendix C. Error Numbers and Messages

C.1.10. Error 13 - Invalid character in program

Explanation:
A character was found outside a literal (quoted) string that is not a whitespace character or one of the valid alphanumeric and special characters.
The associated subcodes are:

001
Incorrect character in program "character" (xhex_character’X)

900
message

C.1.11. Error 14 - Incomplete DO/SELECT/IF

Explanation:
At the end of the program or the string for an INTERPRET instruction, a DO or SELECT instruction was found without a matching END or an IF clause that is not followed by a THEN clause. Putting the name of the control variable on each END closing a controlled loop can help locate this kind of error.
The associated subcodes are:

001
DO instruction on line line_number requires matching END

002
SELECT instruction on line line_number requires matching END

003
THEN on line line_number must be followed by an instruction

004
ELSE on line line_number must be followed by an instruction

901
OTHERWISE on line line_number requires matching END

C.1.12. Error 15 - Invalid hexadecimal or binary string

Explanation:
Hexadecimal strings must not have leading or trailing whitespace characters and whitespace can only be embedded at byte boundaries. Only the digits 0-9 and the letters a-f and A-F are allowed. The following are valid hexadecimal strings:
Binary strings can have whitespace only at the boundaries of groups of four binary digits. Only the digits 0 and 1 are allowed. These are valid binary strings:

 `'1011'b`
 `'110 1101'b`
 `'101101 11010011'b`

You might have mistyped one of the digits, for example, typing a letter O instead of the number 0. Or you might have used the one-character symbol X or B (the name of the variable X or B, respectively) after a literal string when the string is not intended as a hexadecimal or binary specification. In this case, use the explicit concatenation operator (||) to concatenate the string to the value of the symbol.

The associated subcodes are:

  001
  Incorrect location of whitespace character in position position in hexadecimal string

  002
  Incorrect location of whitespace character in position position in binary string

  003
  Only 0-9, a-f, A-F, and whitespace characters are valid in a hexadecimal string; found "character"

  004
  Only 0, 1, and whitespace characters are valid in a binary string; found "character"

### C.1.13. Error 16 - Label not found

**Explanation:**

A SIGNAL instruction has been executed or an event for which a trap was set with SIGNAL ON has occurred, and the language processor could not find the label specified. You might have mistyped the label or forgotten to include it.

The associated subcodes are:

  001
  Label "label_name" not found
C.1.14. Error 17 - Unexpected PROCEDURE

Explanation:
A PROCEDURE instruction was encountered at an incorrect position. This could occur because no internal routines are active or because the PROCEDURE instruction was not the first instruction processed after the CALL instruction or function call. One cause for this error is dropping through to an internal routine, rather than calling it with a CALL instruction or a function call.

The associated subcodes are:

001
PROCEDURE is valid only when it is the first instruction executed after an internal CALL or function invocation

901
INTERPRET data must not contain PROCEDURE

C.1.15. Error 18 - THEN expected

Explanation:
A THEN clause must follow each REXX IF or WHEN clause. The language processor found another clause before it found a THEN clause.

The associated subcodes are:

001
IF instruction on line line_number requires matching THEN clause

002
WHEN instruction on line line_number requires matching THEN clause

C.1.16. Error 19 - String or symbol expected

Explanation:
A symbol or string was expected after the CALL or SIGNAL keywords but none was found. You might have omitted the string or symbol or inserted a special character (such as a parenthesis).

The associated subcodes are:

001
String or symbol expected after ADDRESS keyword

002
String or symbol expected after CALL keyword
003  String or symbol expected after NAME keyword
004  String or symbol expected after SIGNAL keyword
006  String or symbol expected after TRACE keyword
007  String or symbol expected after PARSE keyword
900  message
901  String or symbol expected after ::CLASS keyword
902  String or symbol expected after ::METHOD keyword
903  String or symbol expected after ::ROUTINE keyword
904  String or symbol expected after ::REQUIRES keyword
905  String or symbol expected after EXTERNAL keyword
906  String or symbol expected after METACLASS keyword
907  String or symbol expected after SUBCLASS keyword
908  String or symbol expected after INHERIT keyword
909  String or symbol expected after tilde (~)
911  String or symbol expected after superclass colon (:)
Appendix C. Error Numbers and Messages

912
String or symbol expected after STREAM keyword

913
String or symbol expected after MIXINCLASS keyword

914
String or symbol expected as ::ATTRIBUTE directive name

915
String or symbol expected as ::CONSTANT directive name

916
String or symbol expected as ::CONSTANT value

917
String or symbol expected as DIGITS value

918
String or symbol expected as FUZZ value

919
String or symbol expected as TRACE value

C.1.17. Error 20 - Symbol expected

Explanation:
A symbol is expected after CALL ON, CALL OFF, END, ITERATE, LEAVE, NUMERIC, PARSE, SIGNAL ON, or SIGNAL OFF. Also, a list of symbols or variable references is expected after DROP, EXPOSE, and PROCEDURE EXPOSE. Either there was no symbol when one was required or the language processor found another token.

The associated subcodes are:

900
message

901
Symbol expected after DROP keyword

902
Symbol expected after EXPOSE keyword

903
Symbol expected after PARSE keyword
Appendix C. Error Numbers and Messages

904
Symbol expected after PARSE VAR

905
NUMERIC must be followed by one of the keywords DIGITS, FORM, or FUZZ; found "symbol"

906
Symbol expected after "(" of a variable reference

907
Symbol expected after LEAVE keyword

908
Symbol expected after ITERATE keyword

909
Symbol expected after END keyword

911
Symbol expected after ON keyword

912
Symbol expected after OFF keyword

913
Symbol expected after USE ARG

914
Symbol expected after RAISE keyword

915
Symbol expected after USER keyword

916
Symbol expected after ::

917
Symbol expected after superclass colon (::)

918
Symbol expected after LABEL keyword
C.1.18. Error 21 - Invalid data on end of clause

Explanation:
A clause such as SELECT or NOP is followed by a token other than a comment.
The associated subcodes are:

900  
message

901  
Data must not follow the NOP keyword; found "data"

902  
Data must not follow the SELECT keyword; found "data"

903  
Data must not follow the NAME keyword; found "data"

904  
Data must not follow the condition name; found "data"

905  
Data must not follow the SIGNAL label name; found "data"

906  
Data must not follow the TRACE setting; found "data"

907  
Data must not follow the LEAVE control variable name; found "data"

908  
Data must not follow the ITERATE control variable name; found "data"

909  
Data must not follow the END control variable name; found "data"

911  
Data must not follow the NUMERIC FORM specification; found "data"

912  
Data must not follow the GUARD OFF specification; found "data"

913  
Data must not follow the ::CONSTANT value; found "data"
C.1.19. Error 22 - Invalid character string

Explanation:
A literal string contains character codes that are not valid. This might be because some characters are not possible, or because the character set is extended and certain character combinations are not allowed.
The associated subcodes are:

001
  Incorrect character string "character_string" ('hex_string’X)
900
  message
901
  Incorrect double-byte character

C.1.20. Error 23 - Invalid data string

Explanation:
A data string (that is, the result of an expression) contains character codes that are not valid. This might be because some characters are not possible, or because the character set is extended and certain character combinations are not allowed.
The associated subcodes are:

001
  Incorrect data string "string" ('hex_string’X)
900
  message

C.1.21. Error 24 - Invalid TRACE request

Explanation:
This message is issued when:

• The option on a TRACE instruction or the argument to the built-in function does not start with A, C, E, F, I, L, N, O, or R.
• In interactive debugging, you entered a number that is not a whole number.

The associated subcodes are:
Appendix C. Error Numbers and Messages

001
TRACE request letter must be one of "ACEFILNOR"; found "value"

901
Numeric TRACE requests are valid only from interactive debugging

C.1.22. Error 25 - Invalid subkeyword found

Explanation:
An unexpected token was found at his position of an instruction where a particular subkeyword was expected. For example, in a NUMERIC instruction, the second token must be DIGITS, FUZZ, or FORM.

The associated subcodes are:

001
CALL ON must be followed by one of the keywords ERROR, FAILURE, HALT, NOTREADY, USER, or ANY; found "word"

002
CALL OFF must be followed by one of the keywords ERROR, FAILURE, HALT, NOTREADY, USER, or ANY; found "word"

003
SIGNAL ON must be followed by one of the keywords ERROR, FAILURE, HALT, LOSTDIGITS, NOTREADY, NOMETHOD, NOSTRING, NOVALUE, SYNTAX, USER, or ANY; found "word"

004
SIGNAL OFF must be followed by one of the keywords ERROR, FAILURE, HALT, LOSTDIGITS, NOTREADY, NOMETHOD, NOSTRING, NOVALUE, SYNTAX, USER, or ANY; found "word"

011
NUMERIC FORM must be followed by one of the keywords SCIENTIFIC or ENGINEERING; found "word"

012
PARSE must be followed by one of the keywords ARG, LINEIN, PULL, SOURCE, VALUE, VAR, or VERSION; found "word"

015
NUMERIC must be followed by one of the keywords DIGITS, FORM, or FUZZ; found "word"

017
PROCEDURE must be followed by the keyword EXPOSE or nothing; found "word"

C.1.23. Error 26 - Invalid whole number

Explanation:
An expression was found that did not evaluate to a whole number or is greater than the limit (the default is 999,999,999 for 32-bit system and 999,999,999,999,999,999 for 64-bit systems):

- The positional patterns in parsing templates (including variable positional patterns)
- The operand to the right of the power operator
- The values of exprr and exprf in the DO instruction
- The values given for DIGITS or FUZZ in the NUMERIC instruction
- The number used in the option of the TRACE setting This error is also raised if the value is not permitted (for example, a negative repetition count in a DO instruction), or the division performed during an integer divide or remainder operation does not result in a whole number.

The associated subcodes are:
Appendix C. Error Numbers and Messages

002
Value of repetition count expression in DO instruction must be zero or a positive whole number; found "value"

003
Value of FOR expression in DO instruction must be zero or a positive whole number; found "value"

004
Positional pattern of PARSE template must be a whole number; found "value"

005
DIGITS value must be a positive whole number; found "value"

006
FUZZ value must be zero or a positive whole number; found "value"

007
Number used in TRACE setting must be a whole number; found "value"

008
Operand to the right of the power operator (**) must be a whole number; found "value"

011
Result of % operation did not result in a whole number

900
message

901
Result of a method call did not result in a whole number; found "value"

902
Result of a COMPARETO method call did not result in a whole number; found "value"

903
Result of a COMPARE method call did not result in a whole number; found "value"

C.1.24. Error 27 - Invalid DO syntax
Explanation:
Appendix C. Error Numbers and Messages

A syntax error was found in the DO instruction. You probably used BY, TO, FOR, WHILE, or UNTIL twice, used a WHILE and an UNTIL, or used BY, TO, or FOR when there is no control variable specified.

The associated subcodes are:

001

WHILE and UNTIL keywords cannot be used on the same DO loop

901

Incorrect data following FOREVER keyword on the DO loop; found "data"

902

DO keyword keyword can be specified only once

C.1.25. Error 28 - Invalid LEAVE or ITERATE

Explanation:

A LEAVE or ITERATE instruction was found at an incorrect position. Either no loop was active, or the name specified on the instruction did not match the control variable of any active loop. Note that internal routine calls and the INTERPRET instruction protect DO loops by making them inactive. Therefore, for example, a LEAVE instruction in a subroutine cannot affect a DO loop in the calling routine. You probably tried to use the SIGNAL instruction to transfer control within or into a loop. Because a SIGNAL instruction ends all active loops, any ITERATE or LEAVE instruction causes this message.

The associated subcodes are:

001

LEAVE is valid only within a repetitive loop or labeled block instruction

002

ITERATE is valid only within a repetitive loop

003

Symbol following LEAVE ("symbol") must either match the label of a current loop or block instruction.

004

Symbol following ITERATE ("symbol") must either match the label of a current loop or be omitted

005

Symbol following ITERATE ("symbol") does not match a repetitive block instruction
Appendix C. Error Numbers and Messages

C.1.26. Error 29 - Environment name too long

Explanation:
The environment name specified on the ADDRESS instruction is longer than permitted for the system under which the interpreter is running.
The associated subcodes are:

001
Environment name exceeds limit characters; found "environment_name"

C.1.27. Error 30 - Name or string too long

Explanation:
A variable name, label name, literal (quoted) string has exceeded the allowed limit of 250 characters. The limit for names includes any substitutions. A possible cause of this error is if you use a period (.) in a name, causing an unexpected substitution. Leaving off an ending quotation mark for a literal string, or putting a single quotation mark in a string, can cause this error because several clauses can be included in the string. For example, write the string ‘don’t’ as ‘don’t’ or “don’t”.
The associated subcodes are:

001
Name exceeds 250 characters: "name"
002
Literal string exceeds 250 characters: "string"
900
message
901
Hexadecimal literal string exceeds 250 characters "string"
902
Binary literal string exceeds 250 characters "string"

C.1.28. Error 31 - Name starts with number or "."

Explanation:
A variable was found whose name begins with a numeric digit or a period. You cannot assign a value to such a variable because you could then redefine numeric constants.
The associated subcodes are:
Appendix C. Error Numbers and Messages

001
A value cannot be assigned to a number; found "number"

002
Variable symbol must not start with a number; found "symbol"

003
Variable symbol must not start with a "."; found "symbol"

900
message

C.1.29. Error 33 - Invalid expression result

Explanation:
The result of an expression was found not to be valid in the context in which it was used.
The associated subcodes are:

001
Value of NUMERIC DIGITS ("value") must exceed value of NUMERIC FUZZ ("value")

002
Value of NUMERIC DIGITS ("value") must not exceed value

900
message

901
Incorrect expression result following VALUE keyword of ADDRESS instruction

902
Incorrect expression result following VALUE keyword of SIGNAL instruction

903
Incorrect expression result following VALUE keyword of TRACE instruction

904
Incorrect expression result following SYNTAX keyword of RAISE instruction

C.1.30. Error 34 - Logical value not 0 or 1

Explanation:
An expression was found in an IF, WHEN, DO WHILE, or DO UNTIL phrase that did not result in a 0 or 1. Any value operated on by a logical operator must result in a 0 or 1. For example, the phrase If result then exit rc fails if result has a value other than 0 or 1.

The associated subcodes are:

001
Value of expression following IF keyword must be exactly "0" or "1"; found "value"

002
Value of expression following WHEN keyword must be exactly "0" or "1"; found "value"

003
Value of expression following WHILE keyword must be exactly "0" or "1"; found "value"

004
Value of expression following UNTIL keyword must be exactly "0" or "1"; found "value"

005
Value of expression to the left of the logical operator "operator" must be exactly "0" or "1"; found "value"

006
Value of logical list expression element must be exactly "0" or "1"; found "value"

900
message

901
Logical value must be exactly "0" or "1"; found "value"

902
Value of expression following GUARD keyword must be exactly "0" or "1"; found "value"

903
Authorization return value must be exactly "0" or "1"; found "value"

904
Property logical value must be exactly "0", "1", "true", or "false"; found "value"

**C.1.31. Error 35 - Invalid expression**

**Explanation:**
An expression contains a grammatical error. Possible causes:
Appendix C. Error Numbers and Messages

- An expression is missing when one is required
- You ended an expression with an operator
- You specified, in an expression, two operators next to one another with nothing in between them
- You did not specify a right parenthesis when one was required
- You used special characters (such as operators) in an intended character expression without enclosing them in quotation marks

The associated subcodes are:

001
Incorrect expression detected at "token"

900
message

901
Prefix operator "operator" is not followed by an expression term

902
Missing conditional expression following IF keyword

903
Missing conditional expression following WHEN keyword

904
Missing initial expression for DO control variable

905
Missing expression following BY keyword

906
Missing expression following TO keyword

907
Missing expression following FOR keyword

908
Missing expression following WHILE keyword

909
Missing expression following UNTIL keyword
Appendix C. Error Numbers and Messages

911
Missing expression following OVER keyword

912
Missing expression following INTERPRET keyword

913
Missing expression following OPTIONS keyword

914
Missing expression following VALUE keyword of an ADDRESS instruction

915
Missing expression following VALUE keyword of a SIGNAL instruction

916
Missing expression following VALUE keyword of a TRACE instruction

917
Missing expression following VALUE keyword of a NUMERIC FORM instruction

918
Missing expression following assignment instruction

919
Operator "operator" is not followed by an expression term

921
Missing expression following GUARD keyword

922
Missing expression following DESCRIPTION keyword of a RAISE instruction

923
Missing expression following ADDITIONAL keyword of a RAISE instruction

924
Missing "(" on expression list of the ARRAY keyword

925
Missing expression following TO keyword of a FORWARD instruction

926
Missing expression following ARGUMENTS keyword of a FORWARD instruction
Appendix C. Error Numbers and Messages

927
Missing expression following MESSAGE keyword of a FORWARD instruction

928
Missing expression following CLASS keyword of a FORWARD instruction

929
Missing expression in logical_expression_list

930
Missing expression following "=" token of a USE STRICT ARG instruction

C.1.32. Error 36 - Unmatched "(" or "[" in expression

Explanation:
A matched parenthesis or bracket was found within an expression. There are more left parentheses than right parentheses or more left brackets than right brackets. To include a single parenthesis in a command, enclose it in quotation marks.

The associated subcodes are:

900
message

901
Left parenthesis "(" in position position on line line_number requires a corresponding right parenthesis ")"

902
Square bracket "[" in position position on line line_number requires a corresponding right square bracket "]"

C.1.33. Error 37 - Unexpected ",", ")", or "]"

Explanation:
Either a comma was found outside a function invocation, or there are too many right parentheses or right square brackets in an expression. To include a comma in a character expression, enclose it in quotation marks. For example, write the instruction:

Say Enter A, B, or C

as follows:

Say 'Enter A, B, or C'
Appendix C. Error Numbers and Messages

The associated subcodes are:

001
  Unexpected ",,"

002
  Unmatched ")" in expression

900
  message

901
  Unexpected "]"

C.1.34. Error 38 - Invalid template or pattern

Explanation:
A special character that is not allowed within a parsing template (for example, "%") has been found, or the syntax of a variable pattern is incorrect (that is, no symbol was found after a left parenthesis). This message is also issued if you omit the WITH subkeyword in a PARSE VALUE instruction.

The associated subcodes are:

001
  Incorrect PARSE template detected at "column_position"

002
  Incorrect PARSE position detected at "column_position"

003
  PARSE VALUE instruction requires WITH keyword

900
  message

901
  Missing PARSE relative position

C.1.35. Error 39 - Evaluation stack overflow

Explanation:
The expression is too complex to be evaluated by the language processor.
C.1.36. Error 40 - Incorrect call to routine

**Explanation:**
An incorrect call to a routine was found. Possible causes:

- You passed incorrect data (arguments) to the built-in or external routine.
- You passed too many arguments to the built-in, external, or internal routine.
- The external routine called was not compatible with the language processor.

If you did not try to call a routine, you might have a symbol or a string adjacent to a "(" when you meant it to be separated by a blank or other operator. The language processor would treat this as a function call. For example, write `TIME(4+5)` as follows: `TIME*(4+5)`

The associated subcodes are:

001

- External routine "routine" failed

003

- Not enough arguments in invocation of routine; minimum expected is `number`

004

- Too many arguments in invocation of routine; maximum expected is `number`

005

- Missing argument in invocation of routine; argument `argument_number` is required

011

- `function_name` argument `argument_number` must be a number; found "value"

012

- `function_name` argument `argument_number` must be a whole number; found "value"

013

- `function_name` argument `argument_number` must be zero or positive; found "value"

014

- `function_name` argument `argument_number` must be positive; found "value"

019

- `function_name` argument 2, "value", is not in the format described by argument 3, "value"

021

- `function_name` argument `argument_number` must not be a null string
Appendix C. Error Numbers and Messages

022
function_name argument argument_number must be a single character or null; found "value"

023
function_name argument argument_number must be a single character; found "value"

024
function_name argument argument_number must be a binary string; found "value"

025
function_name argument argument_number must be a hexadecimal string; found "value"

026
function_name argument argument_number must be a valid symbol; found "value"

027
function_name argument 1 must be a valid stream name; found "value"

029
function_name conversion to format "value" is not allowed

032
RANDOM difference between argument 1 ("value") and argument 2 ("value") must not exceed 999,999,999

033
RANDOM argument 1 ("argument") must be less than or equal to argument 2 ("argument")

034
SOURCELINE argument 1 ("argument") must be less than or equal to the number of lines in the program (argument)

035
X2D argument 1 cannot be expressed as a whole number; found "value"

043
function_name argument number must be a single non-alphanumeric character or the null string; found "value"

044
function_name argument number, "value", is a format incompatible with the separator specified in argument number

900
message
Appendix C. Error Numbers and Messages

901
Result returned by routine is longer than length: "value"

902
function_name argument argument_number must not exceed the whole number limit.

903
function_name argument argument_number must be in the range 0-99; found "value"

904
function_name argument argument_number must be one of values; found "value"

905
TRACE setting letter must be one of "ACEFILNOR"; found "value"

912
function_name argument argument_number must be a single-dimensional array; found "value"

913
function_name argument argument_number must have a string value; found "value"

914
Unknown VALUE function variable environment selector; found "value"

915
function_name cannot be used with QUEUE:

916
Cannot read from a write-only property.

917
Cannot write to a read-only property or typelib element.

918
Invalid native function signature specification

919
Argument argument must have a stem object or stem name value; found "value"

C.1.37. Error 41 - Bad arithmetic conversion

Explanation:
A term in an arithmetic expression is not a valid number or has an exponent outside the allowed range of whole number range.
You might have mistyped a variable name, or included an arithmetic operator in a character expression without putting it in quotation marks.

The associated subcodes are:

001

Nonnumeric value ("value") used in arithmetic operation

003

Nonnumeric value ("value") used with prefix operator

004

Value of TO expression of DO instruction must be numeric; found "value"

005

Value of BY expression of DO instruction must be numeric; found "value"

006

Value of control variable expression of DO instruction must be numeric; found "value"

007

Exponent exceeds number digits; found "value"

900

message

901

Value of RAISE instruction SYNTAX expression must be numeric; found "value"

**C.1.38. Error 42 - Arithmetic overflow/underflow**

**Explanation:**

The result of an arithmetic operation requires an exponent that is greater than the platform limit of nine digits for 32-bit systems or 18 for 64-bit systems.

This error can occur during the evaluation of an expression (often as a result of trying to divide a number by 0) or while stepping a DO loop control variable.

The associated subcodes are:

001

Arithmetic overflow detected at: "value operator value"

002

Arithmetic underflow detected at: "value operator value"
Appendix C. Error Numbers and Messages

003
Arithmetic overflow; divisor must not be zero

900
message

901
Arithmetic overflow; exponent ("exponent") exceeds number digits

902
Arithmetic underflow; exponent ("exponent") exceeds number digits

903
Arithmetic underflow; zero raised to a negative power

C.1.39. Error 43 - Routine not found

Explanation:
A function has been invoked within an expression or a subroutine has been invoked by a CALL, but it cannot be found. Possible reasons:

- The specified label is not in the program
- It is not the name of a built-in function
- The language processor could not locate it externally

Check if you mistyped the name.

If you did not try to call a routine, you might have put a symbol or string adjacent to a "(" when you meant it to be separated by a blank or another operator. The language processor then treats it as a function call. For example, write the string 3(4+5) as 3*(4+5).

The associated subcodes are:

001
Could not find routine "routine"

900
message

901
Could not find routine "routine" for ::REQUIRES
C.1.40. Error 44 - Function or message did not return data

Explanation:
The language processor called an external routine within an expression. The routine seemed to end without error, but it did not return data for use in the expression.
You might have specified the name of a program that is not intended for use as a REXX function. Call it as a command or subroutine instead.
The associated subcodes are:

001
  No data returned from function "function"
900
  message

C.1.41. Error 45 - No data specified on function RETURN

Explanation:
A REXX program has been called as a function, but returned without passing back any data.
The associated subcodes are:

001
  Data expected on RETURN instruction because routine "routine" was called as a function

C.1.42. Error 46 - Invalid variable reference

Explanation:
Within an ARG, DROP, EXPOSE, PARSE, PULL, or PROCEDURE instruction, the syntax of a variable reference (a variable whose value is to be used, indicated by its name being enclosed in parentheses) is incorrect. The right parenthesis that must immediately follow the variable name might be missing or the variable name might be misspelled.
The associated subcodes are:

001
  Extra token ("token") found in variable reference list; ")" expected
900
  message
901
  Missing ")" in variable reference
C.1.43. Error 47 - Unexpected label

Explanation:
A label was used in the expression being evaluated for an INTERPRET instruction or in an expression entered during interactive debugging.

The associated subcodes are:

001
INTERPRET data must not contain labels; found "label"

C.1.44. Error 48 - Failure in system service

Explanation:
The language processor stopped processing the program because a system service, such as stream input or output or the manipulation of the external data queue, has failed to work correctly.

The associated subcodes are:

001
Failure in system service: service
900
message

C.1.45. Error 49 - Interpretation error

Explanation:
A severe error was detected in the language processor or execution process during internal self-consistency checks.

The associated subcodes are:

001
Interpretation error: unexpected failure initializing the interpreter
900
message
C.1.46. Error 88 - Invalid argument

Explanation:
An argument passed to a method, function, or routine was not valid.
The associated subcodes are:

900
message

901
Missing argument; argument argument is required

902
Argument argument must be a number; found "value"

903
Argument argument must be a whole number; found "value"

904
Argument argument must be zero or a positive whole number; found "value"

905
Argument argument must be a positive whole number; found "value"

906
Argument argument must not exceed limit; found "value"

907
Argument argument must be in the range min to max; found "value"

908
Argument argument must not be a null string

909
Argument argument must have a string value

910
Argument argument is an incorrect pad or character argument; found "value"

911
Argument argument is an incorrect length argument; found "value"

912
Argument argument is an incorrect position argument; found "value"
Appendix C. Error Numbers and Messages

913
Argument argument must have a single-dimensional array value

914
Argument argument must be of the class class

915
Argument argument could not be converted to type type

916
Argument argument must be one of values; found "value"

917
Argument argument reason

918
Argument argument is not in a valid format; found "value"

919
Argument argument is not in valid pointer format; found "value"

920
Argument argument must have a stem object or stem name value; found "value"

921
Argument argument must be a valid double value; found "value"

922
Too many arguments in invocation; number expected

C.1.47. Error 89 - Variable or message term expected

Explanation:
An instruction was expecting either a single Rexx variable symbol or a message term to be used for an assignment.

The associated subcodes are:

001
The USE instruction requires a comma-separated list of variables or assignment message terms

002
The PARSE was expecting a variable or a message term.
C.1.48. Error 90 - External name not found

Explanation:
An external class, method, or routine (specified with the EXTERNAL option on a ::CLASS, ::METHOD, or ::ROUTINE directive, or as a second argument on a NEW message to the Method class) cannot be found.
The associated subcodes are:

900  
message

997
    Unable to find external class "class"

998
    Unable to find external method "method"

999
    Unable to find external routine "routine"

C.1.49. Error 91 - No result object

Explanation:
A message term requires a result object, but the method did not return one.
The associated subcodes are:

900  
message

999
    Message "message" did not return a result

C.1.50. Error 92 - OLE error

The associated subcodes are:

900  
message

901
    An unknown OLE error occurred (HRESULT=hresult).
Appendix C. Error Numbers and Messages

902
Cannot convert OLE VARIANT to REXX object: The conversion of the VARIANT type `varianttype` into a REXX object failed.

903
Cannot convert REXX object to OLE VARIANT: The conversion of `rexx_object` into a VARIANT failed.

904
The number of elements provided to the method or property is different from the number of parameters accepted by it.

905
One of the parameters is not a valid VARIANT type.

906
OLE exception: `exc_name`

907
The requested method does not exist, or you tried to set the value of a read-only property.

908
One of the parameters could not be coerced to the desired type.

909
One or more of the parameters could not be coerced to the desired type. The first parameter with incorrect type is argument `index`.

910
A required parameter was omitted.

911
Could not create OLE instance.

912
The object invoked has disconnected from its clients.

C.1.51. Error 93 - Incorrect call to method

Explanation:
The specified method, built-in function, or external routine exists, but you used it incorrectly.
The associated subcodes are:
Appendix C. Error Numbers and Messages

900
  message

901
  Not enough arguments in method; number expected

902
  Too many arguments in invocation of method; number expected

903
  Missing argument in method; argument argument is required

904
  Method argument argument must be a number; found "value"

905
  Method argument argument must be a whole number; found "value"

906
  Method argument argument must be zero or a positive whole number; found "value"

907
  Method argument argument must be a positive whole number; found "value"

908
  Method argument argument must not exceed limit; found "value"

909
  Method argument argument must be in the range 0-99; found "value"

911
  Method argument argument must not be null

912
  Method argument argument must be a hexadecimal string; found "value"

913
  Method argument argument must be a valid symbol; found "value"

914
  Method argument argument must be one of arguments; found "value"

915
  Method option must be one of "arguments"; found "value"
Appendix C. Error Numbers and Messages

916
Method argument argument must have a string value

917
Method method does not exist

918
Incorrect list index "index"

919
Incorrect array position "position"

921
Argument missing on binary operator

922
Incorrect pad or character argument specified; found "value"

923
Incorrect length argument specified; found "value"

924
Incorrect position argument specified; found "value"

925
Not enough subscripts for array; number expected

926
Too many subscripts for array; number expected

927
Length must be specified to convert a negative value

928
D2X value must be a valid whole number; found "value"

929
D2C value must be a valid whole number; found "value"

931
Incorrect location of whitespace character in position position in hexadecimal string

932
Incorrect location of whitespace character in position position in binary string
Appendix C. Error Numbers and Messages

933
Only 0-9, a-f, A-F, and whitespace characters are valid in a hexadecimal string; character found "character"

934
Only 0, 1, and whitespace characters are valid in a binary string; character found "character"

935
X2D result is not a valid whole number with NUMERIC DIGITS digits

936
C2D result is not a valid whole number with NUMERIC DIGITS digits

937
No more supplier items available

938
Method argument argument must have a string value

939
Method argument argument must have a single-dimensional array value

941
Exponent "exponent" is too large for number spaces

942
Integer part "integer" is too large for number spaces

943
method method target must be a number; found "value"

944
Method argument argument must be a message object

945
Missing argument in message array; argument argument is required

946
A message array must be a single-dimensional array with 2 elements

947
Method SECTION can be used only on single-dimensional arrays

948
Method argument argument must be of the class class
Appendix C. Error Numbers and Messages

949
The index and value objects must be the same for PUT to an index-only collection

951
Incorrect alarm time; found "time"

952
Method argument \textit{argument} is an array and does not contain all string values

953
Method argument \textit{argument} could not be converted to type \textit{type}

954
Method \textit{method} can be used only on a single-dimensional array

956
Element \textit{element} of the array must be a string

957
Element \textit{element} of the array must be a subclass of the target object

958
Positioning of transient streams is not valid

959
An array cannot contain more than 99,999,999 elements

961
Method argument \textit{argument} must have a string value or an array value

962
Invalid Base 64 encoded string.

963
Call to unsupported or unimplemented method

964
\textit{Application error: message}

965
Method \textit{name} is ABSTRACT and cannot be directly invoked

966
Incorrect queue index "\textit{index}"

Appendix C. Error Numbers and Messages

967
NEW method is not supported for the name class

968
Invalid native method signature specification

969
Method argument argument must have a stem object value; found "value"

970
COPY method is not supported for object object

C.1.52. Error 97 - Object method not found

Explanation:
The object does not have a method with the given name. A frequent cause of this error is an uninitialized variable.
The associated subcodes are:

001
Object "object" does not understand message "message"

900
message

C.1.53. Error 98 - Execution error

Explanation:
The language processor detected a specific error during execution. The associated error gives the reason for the error.
The associated subcodes are:

900
message

902
Unable to convert object "object" to a double-float value

903
Unable to load library "name"
Appendix C. Error Numbers and Messages

904
Abnormal termination occurred

905
Deadlock detected on a guarded method

906
Incorrect object reference detected

907
Object of type "type" was required

908
Metaclass "metaclass" not found

909
Class "class" not found

911
Cyclic inheritance in program "program"

913
Unable to convert object "object" to a single-dimensional array value

914
Unable to convert object "object" to a string value

915
A message object cannot be sent more than one SEND or START message

916
Message object "object" received an error from message "message"

917
Incorrect condition object received for RAISE OBJECT; found "value"

918
No active condition available for PROPAGATE

919
Unable to convert object "object" to a method

935
REPLY can be issued only once per method invocation
RETURN cannot return a value after a REPLY

EXIT cannot return a value after a REPLY

Message search overrides can be used only from methods of the target object

Additional information for SYNTAX errors must be a single-dimensional array of values

Unknown error number specified on RAISE SYNTAX; found "number"

Class "class" must be a MIXINCLASS for INHERIT

Class "class" is not a subclass of "class" base class "class"

Class "class" cannot inherit from itself, a superclass, or a subclass ("class")

Class "class" has not inherited class "class"

FORWARD arguments must be a single-dimensional array of values

FORWARD can only be issued in an object method invocation

Authorization failure: value

Concurrency not supported

Missing array element at position position

Stem object default value cannot be another stem object
Appendix C. Error Numbers and Messages

978
Unable to load method "name" from library "library"

979
Unable to load routine "name" from library "library"

980
Unable to load native routine "name"

981
Target RexxContext is no longer active

982
Library "name" is not compatible with current interpreter version.

983
Execution thread does not match API thread context.

C.1.54. Error 99 - Translation error

Explanation:
An error was detected in the language syntax. The associated error subcode identifies the syntax error. The associated subcodes are:

900
message

901
Duplicate ::CLASS directive instruction

902
Duplicate ::METHOD directive instruction

903
Duplicate ::ROUTINE directive instruction

904
Duplicate ::REQUIRES directive instruction

905
CLASS keyword on ::METHOD directive requires a matching ::CLASS directive
Appendix C. Error Numbers and Messages

907
EXPOSE must be the first instruction executed after a method invocation

908
INTERPRET data must not contain EXPOSE

909
GUARD must be the first instruction executed after EXPOSE or USE

911
GUARD can only be issued in an object method invocation

912
INTERPRET data must not contain GUARD

913
GUARD instruction did not include references to exposed variables

914
INTERPRET data must not contain directive instructions

915
INTERPRET data must not contain USE

916
Unrecognized directive instruction

917
Incorrect external directive name "method"

918
USE ARG requires a "," between variable names; found "token"

919
REPLY can only be issued in an object method invocation

921
Incorrect program line in method source array

922
::REQUIRES directives must appear before other directive instructions

C.2. RXSUBCOM Utility Program

RXSUBCOM issues the following errors:

C.2.1. Error 116 - The RXSUBCOM parameter REGISTER is incorrect.

Explanation:
RXSUBCOM REGISTER requires the following parameters:

RXSUBCOM REGISTER Environment_Name Dll_Name Procedure_Name

Environment_Name
is the name of the subcommand handler.
Appendix C. Error Numbers and Messages

.C.2.2. Error 117 - The RXSUBCOM parameter DROP is incorrect.

Explanation:
RXSUBCOM DROP requires that the subcommand handler name be specified.

RXSUBCOM DROP Environment_Name [DII_Name]

Environment_Name
    is the name of the subcommand handler.

.DII_Name
    is the name of the file containing the subcommand handler routine (optional).

.C.2.3. Error 118 - The RXSUBCOM parameter LOAD is incorrect.

Explanation:
RXSUBCOM LOAD requires that the subcommand handler name be specified.

RXSUBCOM LOAD Environment_Name [DII_Name]

Environment_Name
    is the name of the subcommand handler.

.DII_Name
    is the name of the file containing the subcommand handler routine (optional).
Appendix C. Error Numbers and Messages

C.2.4. Error 125 - The RXSUBCOM parameter QUERY is incorrect.

Explanation:
RXSUBCOM QUERY requires the environment name be specified.

RXSUBCOM QUERY Environment_Name [DII_Name]

Environment_Name

is the name of the subcommand handler.

.DII_Name

is the name of the file containing the subcommand handler routine (optional).

C.3. RXQUEUE Utility Program

RXQUEUE issues the following errors:

C.3.1. Error 119 - The REXX queuing system is not initialized.

Explanation:
The queuing system requires a housekeeping program to run. This program usually runs under the Presentation Manager shell. The program is not running.

C.3.2. Error 120 - The size of the data is incorrect.

Explanation:
The data supplied to the RXQUEUE command is too long. The RXQUEUE program accepts data records containing 0 - 65472 bytes. A record exceeded the allowable limits.

C.3.3. Error 121 - Storage for data queues is exhausted.

Explanation:
The queuing system is out of memory. No more storage is available to store queued data.

C.3.4. Error 122 - The name %1 is not a valid queue name.

Explanation:
The queue name contains an invalid character. Only the following characters can appear in queue names:

'A' .. 'Z', '0' .. '9', '.', '!', '?', '_'

C.3.5. Error 123 - The queue access mode is not correct.

Explanation:
An internal error occurred in RXQUEUE. The RXQUEUE program tried to access a queue with an incorrect access mode. Correct access modes are LIFO and FIFO.

C.3.6. Error 124 - The queue %1 does not exist.

Explanation:
The command attempted to access a nonexistent queue.

C.3.7. Error 131 - The syntax of the command is incorrect

C.3.8. Error 132 - System error occurred while processing the command

C.4. RexxC Utility Program

When RexxC encounters a syntax error in a Rexx program while tokenizing or syntax checking it, RexxC returns the negated ooRexx error code. In addition, RexxC issues the following errors:

C.4.1. Error 127 - The REXXC command parameters are incorrect.

Explanation:
The REXXC utility was invoked with zero or more than three parameters. REXXC accepts the following parameters:

- To check the syntax of a REXX program: REXXC Program_name [-s]
Appendix C. Error Numbers and Messages

- To convert a REXX program into a sourceless executable file: REXXC Program_name
  Output_file_name [-s]
- The -s option will suppress the copyright banner.

C.4.2. Error 128 - Output file name must be different from input file name.

C.4.3. Error 129 - SYNTAX: REXXC InProgramName
[OutProgramName] [/S]

C.4.4. Error 130 - Without OutProgramName REXXC only performs a syntax check

C.4.5. Error 133 - SYNTAX: REXXC InProgramName
[OutProgramName] [-s]
Appendix D. Notices

Any reference to a non-open source product, program, or service is not intended to state or imply that only non-open source product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any Rexx Language Association (RexxLA) intellectual property right may be used instead. However, it is the user’s responsibility to evaluate and verify the operation of any non-open source product, program, or service.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurement may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-open source products was obtained from the suppliers of those products, their published announcements or other publicly available sources. RexxLA has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-RexxLA packages. Questions on the capabilities of non-RexxLA packages should be addressed to the suppliers of those products.

All statements regarding RexxLA’s future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

D.2. Source Code For This Document

The source code for this document is available under the terms of the Common Public License v1.0 which accompanies this distribution and is available in the appendix Common Public License Version 1.0. The source code itself is available at http://sourceforge.net/project/showfiles.php?group_id=119701.

The source code for this document is maintained in DocBook SGML/XML format.
Appendix E. Common Public License Version 1.0

THE ACCOMPANYING PROGRAM IS PROVIDED UNDER THE TERMS OF THIS COMMON PUBLIC LICENSE ("AGREEMENT"). ANY USE, REPRODUCTION OR DISTRIBUTION OF THE PROGRAM CONSTITUTES RECIPIENT’S ACCEPTANCE OF THIS AGREEMENT.

E.1. Definitions

"Contribution" means:

1. in the case of the initial Contributor, the initial code and documentation distributed under this Agreement, and
2. in the case of each subsequent Contributor:
   a. changes to the Program, and
   b. additions to the Program;

where such changes and/or additions to the Program originate from and are distributed by that particular Contributor. A Contribution ‘originates’ from a Contributor if it was added to the Program by such Contributor itself or anyone acting on such Contributor’s behalf. Contributions do not include additions to the Program which: (i) are separate modules of software distributed in conjunction with the Program under their own license agreement, and (ii) are not derivative works of the Program.

"Contributor" means any person or entity that distributes the Program.

"Licensed Patents ” mean patent claims licensable by a Contributor which are necessarily infringed by the use or sale of its Contribution alone or when combined with the Program.

"Program" means the Contributions distributed in accordance with this Agreement.

"Recipient” means anyone who receives the Program under this Agreement, including all Contributors.

E.2. Grant of Rights

1. Subject to the terms of this Agreement, each Contributor hereby grants Recipient a non-exclusive, worldwide, royalty-free copyright license to reproduce, prepare derivative works of, publicly display, publicly perform, distribute and sublicense the Contribution of such Contributor, if any, and such derivative works, in source code and object code form.

2. Subject to the terms of this Agreement, each Contributor hereby grants Recipient a non-exclusive, worldwide, royalty-free patent license under Licensed Patents to make, use, sell, offer to sell, import and otherwise transfer the Contribution of such Contributor, if any, in source code and object code form. This patent license shall apply to the combination of the Contribution and the Program if, at the time the Contribution is added by the Contributor, such addition of the Contribution causes such
Appendix E. Common Public License Version 1.0

combination to be covered by the Licensed Patents. The patent license shall not apply to any other combinations which include the Contribution. No hardware per se is licensed hereunder.

3. Recipient understands that although each Contributor grants the licenses to its Contributions set forth herein, no assurances are provided by any Contributor that the Program does not infringe the patent or other intellectual property rights of any other entity. Each Contributor disclaims any liability to Recipient for claims brought by any other entity based on infringement of intellectual property rights or otherwise. As a condition to exercising the rights and licenses granted hereunder, each Recipient hereby assumes sole responsibility to secure any other intellectual property rights needed, if any. For example, if a third party patent license is required to allow Recipient to distribute the Program, it is Recipient’s responsibility to acquire that license before distributing the Program.

4. Each Contributor represents that to its knowledge it has sufficient copyright rights in its Contribution, if any, to grant the copyright license set forth in this Agreement.

E.3. Requirements

A Contributor may choose to distribute the Program in object code form under its own license agreement, provided that:

1. it complies with the terms and conditions of this Agreement; and

2. its license agreement:
   a. effectively disclaims on behalf of all Contributors all warranties and conditions, express and implied, including warranties or conditions of title and non-infringement, and implied warranties or conditions of merchantability and fitness for a particular purpose;
   b. effectively excludes on behalf of all Contributors all liability for damages, including direct, indirect, special, incidental and consequential damages, such as lost profits;
   c. states that any provisions which differ from this Agreement are offered by that Contributor alone and not by any other party; and
   d. states that source code for the Program is available from such Contributor, and informs licensees how to obtain it in a reasonable manner on or through a medium customarily used for software exchange.

When the Program is made available in source code form:

1. it must be made available under this Agreement; and

2. a copy of this Agreement must be included with each copy of the Program.

Contributors may not remove or alter any copyright notices contained within the Program.

Each Contributor must identify itself as the originator of its Contribution, if any, in a manner that reasonably allows subsequent Recipients to identify the originator of the Contribution.
E.4. Commercial Distribution

Commercial distributors of software may accept certain responsibilities with respect to end users, business partners and the like. While this license is intended to facilitate the commercial use of the Program, the Contributor who includes the Program in a commercial product offering should do so in a manner which does not create potential liability for other Contributors. Therefore, if a Contributor includes the Program in a commercial product offering, such Contributor ("Commercial Contributor") hereby agrees to defend and indemnify every other Contributor ("Indemnified Contributor") against any losses, damages and costs (collectively "Losses") arising from claims, lawsuits and other legal actions brought by a third party against the Indemnified Contributor to the extent caused by the acts or omissions of such Commercial Contributor in connection with its distribution of the Program in a commercial product offering. The obligations in this section do not apply to any claims or Losses relating to any actual or alleged intellectual property infringement. In order to qualify, an Indemnified Contributor must: a) promptly notify the Commercial Contributor in writing of such claim, and b) allow the Commercial Contributor to control, and cooperate with the Commercial Contributor in, the defense and any related settlement negotiations. The Indemnified Contributor may participate in any such claim at its own expense.

For example, a Contributor might include the Program in a commercial product offering, Product X. That Contributor is then a Commercial Contributor. If that Commercial Contributor then makes performance claims, or offers warranties related to Product X, those performance claims and warranties are such Commercial Contributor’s responsibility alone. Under this section, the Commercial Contributor would have to defend claims against the other Contributors related to those performance claims and warranties, and if a court requires any other Contributor to pay any damages as a result, the Commercial Contributor must pay those damages.

E.5. No Warranty

EXCEPT AS EXPRESSLY SET FORTH IN THIS AGREEMENT, THE PROGRAM IS PROVIDED ON AN "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, EITHER EXPRESS OR IMPLIED INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OR CONDITIONS OF TITLE, NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Each Recipient is solely responsible for determining the appropriateness of using and distributing the Program and assumes all risks associated with its exercise of rights under this Agreement, including but not limited to the risks and costs of program errors, compliance with applicable laws, damage to or loss of data, programs or equipment, and unavailability or interruption of operations.

E.6. Disclaimer of Liability

EXCEPT AS EXPRESSLY SET FORTH IN THIS AGREEMENT, NEITHER RECIPIENT NOR ANY CONTRIBUTORS SHALL HAVE ANY LIABILITY FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING WITHOUT LIMITATION LOST PROFITS), HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OR DISTRIBUTION OF THE
E.7. General

If any provision of this Agreement is invalid or unenforceable under applicable law, it shall not affect the validity or enforceability of the remainder of the terms of this Agreement, and without further action by the parties hereto, such provision shall be reformed to the minimum extent necessary to make such provision valid and enforceable.

If Recipient institutes patent litigation against a Contributor with respect to a patent applicable to software (including a cross-claim or counterclaim in a lawsuit), then any patent licenses granted by that Contributor to such Recipient under this Agreement shall terminate as of the date such litigation is filed. In addition, if Recipient institutes patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Program itself (excluding combinations of the Program with other software or hardware) infringes such Recipient’s patent(s), then such Recipient’s rights granted under Section 2(b) shall terminate as of the date such litigation is filed.

All Recipient’s rights under this Agreement shall terminate if it fails to comply with any of the material terms or conditions of this Agreement and does not cure such failure in a reasonable period of time after becoming aware of such noncompliance. If all Recipient’s rights under this Agreement terminate, Recipient agrees to cease use and distribution of the Program as soon as reasonably practicable. However, Recipient’s obligations under this Agreement and any licenses granted by Recipient relating to the Program shall continue and survive.

Everyone is permitted to copy and distribute copies of this Agreement, but in order to avoid inconsistency the Agreement is copyrighted and may only be modified in the following manner. The Agreement Steward reserves the right to publish new versions (including revisions) of this Agreement from time to time. No one other than the Agreement Steward has the right to modify this Agreement. IBM is the initial Agreement Steward. IBM may assign the responsibility to serve as the Agreement Steward to a suitable separate entity. Each new version of the Agreement will be given a distinguishing version number. The Program (including Contributions) may always be distributed subject to the version of the Agreement under which it was received. In addition, after a new version of the Agreement is published, Contributor may elect to distribute the Program (including its Contributions) under the new version. Except as expressly stated in Sections 2(a) and 2(b) above, Recipient receives no rights or licenses to the intellectual property of any Contributor under this Agreement, whether expressly, by implication, estoppel or otherwise. All rights in the Program not expressly granted under this Agreement are reserved.

This Agreement is governed by the laws of the State of New York and the intellectual property laws of the United States of America. No party to this Agreement will bring a legal action under this Agreement more than one year after the cause of action arose. Each party waives its rights to a jury trial in any resulting litigation.
